1. Introduction

Phospholipase A2 (PLA2) catalyzes the hydrolysis of the SN-2 acyl ester linkage of phospholipids and producing fatty acids and lysophospholipids. Their activity is one of the rate-limiting steps in the formation of arachidonic acid and in the synthesis of leukotrienes and prostaglandins. These prostaglandins have vital role in carcinogenesis. In the present study structure based drug design approach has applied to the hnps-PLA2 inhibitors. It can be concluded that indole-3-acetamide derivative molecule 13 h was showing better interaction with the active site of hnps-PLA2. The comparative in silico ADME studies proved that 13h molecule could be a potential anticancer drug. Phospholipase is an enzyme that converts phospholipids into fatty acid and other lipophillic-substances. There are four major classes of Phospholipase, termed A, B, C and D. These classes are distinguished by the catalyzing type of reactions. Phospholipase A has two subtypes: Phospholipase A1 which cleaves the SN-1 acyl chain and Phospholipase A2 which cleaves the SN-2 acyl chain.

2. Material and method

Ligand fit (Discovery studio 2.1) software was used for molecular docking studies (Venkatachalam, C.M. et al. 2003). It is based on a cavity detection algorithm and Monte Carlo conformational search algorithm for generating ligand poses consistent with the active site shape. The crystal structure of hnps-PLA2 (1DB4) complex with potent indole inhibitor was determined and used in structure based drug design (Schevitz RW et al 1995). The PDB structure 1DB4 was chosen for our study has 2.20 Å resolution and has RMSD value below 2 Å.

2.1 Ligand and receptor preparation

The hnps-PLA2 inhibitors, 74 indole-3-acetic acid derivatives (Robert D. Dillard et al 1996) were sketched. The structure of all molecules used in the present study was designed on the
basis of the reported scaffold and the substituent table from NCBI pubchem. The Generic
drugs with diverse scaffolds were downloaded from pubchem library. The Hydrogen Bonds
were added and CHARMm force field was applied to all molecules.
The crystal structure of hnps-PLA2 protein (1DB4) was downloaded from the PDB. After
applying CHARMm force field macro molecule hnps-PLA2 was assigned as receptor.
The receptor cavity was searched using flood filling algorithm and partition site was
adjusted for the better fitments of molecule in the partition site of receptor. The
comparative docking studies for all 100 molecules were performed. The determination of
the ligand binding affinity was calculated using Ligscore1, Ligscore2 and Dock score
were used to estimate the ligand-binding energies. In the present study ADME Tox
software was used to study the toxicity of hnps-PLA2 inhibitors. We have used top ten
ranked dock molecule of hnps-PLA2 for the present study. The Hydrogen Bonds were
added and CHARMm force field was applied to all molecules and the ADME properties
were calculated.

3. Result and analysis

In the present study we have taken generic drugs with diverse scaffolds and indole
inhibitors of hnps-PLA2 which were biologically tested and synthesized (Robert D. Dillard
et al 1996). The structure based studies of the molecules described above were carried out
using Discovery Studio. The RMSD value between the top ten ranked (based on docked
energy) reference molecules and hnps-PLA2 was reported around 2A°.
Table 1 had shown the different score values of top ranked ligands against hnsp-SPLA2
receptor. The score values include Ligscore1 and Ligscore2 which is based on protein-
ligand affinity energy (Krammer et al 2005). It has been observed that Ligscore1 (6.16),
Ligscore2 (7.06) were found highest for the 13 h molecule in comparison with the other 100
molecules. During the study it has been observed that molecule 13 h which was found
highest docked energy score 80.47 has high inhibitory concentration (IC50 .03 uM) which
proved that the drugs found most effective in prior experimental studies was also giving
high dock scores.
It has been reported that indole inhibitors when substituted with additional alkyl group at
different positions of indole the efficacy of the compound had increased towards hnps-PLA2
(Lin et al 2003). In the present study the molecules having indole ring proved more efficient
when substituting with other additional groups on indole ring. In comparison with the
binding affinity of the other molecules it has been observed that indole-3- derivatives were
found most effective scaffold. The top 7 Ranked docked molecules had indole ring and a
additional acid side chain on the fifth position with acid group (13h (80.47 J/mol), 41 (71.59
J/mol), 2n (70.59 J/mol), 71 (70.48 J/mol), 7i (68.14 J/mol), 16b (67.71 J/mol), 60a (67.71
J/mol)) It has been observed that indole-3-acetamides series molecule possessed potency
and selectivity as inhibitors of hnps-PLA2 (Robert D. Dillard et al 1996). It was observed that
the top 6 docked molecules (molecule 13h (80.47 J/mol), 41 (71.59 J/mol), 71 (70.48 J/mol),
7i (68.14 J/mol), 16b (67.71 J/mol), 60a (67.71 J/mol)) had 3-acetamide side chain at Indole
ring. The molecule 13 h had oxy propyl phosphonic acid group on fifth position which had
shown strong hydrogen bonding formation with the active site residue histidine of hnps-
SPLA2 receptor. Fig 1.
Fig. 1. Molecule 13h showing hydrogen bonding with histidine
Fig. 2. Molecule 13h
Fig. 3. Molecule 41 showing similarities with mol 13h

The structural similarity of two top ranked dock score molecules suggested that both had 3-indole acetamide ring as basic scaffold and phosphonic acid group which was attached to fifth position of indole and a benzyl ring which was attached to first position of indole. (Fig 2,3)

The top ten ranked dock molecules were chosen for ADME analysis. The ADME properties of 13h were found very satisfactory. The aqueous solubility value was found within optimal range-(4.028) whereas the molecule indomethcin (3.24), indoprofen (3.54) was found not good solubility value. The molecule 16b, 7i, 7l, 60a had poor (3) intestinal absorption level whereas molecule 13 h had very good (0) intestinal absorption level. The Plasma protein binding was found more than 90% for molecule 13 h but it was reported more than 95% for
the molecule 41 and 2n. The Blood Brain Penetration Level for molecule 13h was found to be extremely low (4) level and the cytochrome P450 enzyme (1) level was not found to be inhibited by molecule 13 h. Thus comparing with the other molecules ADME properties 13 h had a good therapeutic index.

4. Conclusion

In the present study it can be concluded that Indole derivative molecule 13 h is proved to better molecule in terms of experimental studies, molecular interaction with hnp-SPLA2 receptor and computational ADME studies. So the present study proved that hnps-PLA2
based inhibitor molecule 13 h (Fig 4) could be a better substitute for NSAID (Non-steroid anti inflammatory drug).

Fig. 4. Showing alternate pathway for inflammation

5. References

"Inflammatory Diseases - A Modern Perspective" represents an extended and thoroughly revised collection of papers on inflammation. This book explores a wide range of topics relevant to inflammation and inflammatory diseases while its main objective is to help in understanding the molecular mechanism and a concrete review of inflammation. One of the interesting things about this book is its diversity in topics which include pharmacology, medicine, rational drug design, microbiology and biochemistry. Each topic focuses on inflammation and its related disease thus giving a unique platform which integrates all the useful information regarding inflammation.
