Voice Activated Appliances for Severely Disabled Persons

Soo-young Suk and Hiroaki Kojima

Advanced Industrial Science and Technology
Japan

1. Introduction

People with severe speech and motor impairment due to cerebral palsy are great difficult to move independently and also cannot control home electric devices. Computer has much to offer people with disability, but the standard human-machine interface (e.g. keyboard and mouse) is inaccessible to this population. In this chapter, we describe a speech recognition interface for the control of powered wheelchair and home automation systems via severely disabled person’s voices. In particular, we consider that our system can be operated by inarticulate speech produced by persons with severe cerebral palsy or quadriplegia in real-environment.

The aim of our research is divided two targets. One is easy to control of various home appliances by voice, and the other is to enable severely disabled person’s movement independently using voice activated powered wheelchair. At first, Home automation system product for intelligent home is increasingly getting very common by the help of intelligent home technologies that increased easy, safety and comfort. Moreover, home automation is an absolute benefit and can improve the quality of life for the user. Home automation houses have been developed to apply new technologies in real environment, such as Welfare Techno Houses (Tamura et al., 2007), Intelligent Sweet Home (Park et al., 2007), Smart House (West et al., 2005). Interfaces based on gestures or voices have been widely used for home automation. However, gesture recognition based on vision technologies depends critically on the external illumination conditions. And gesture recognition is difficult or impossible for people suffering from severe motor impairments, such as paraplegia and tremors. Recently, a voice-activated system using commercial voice-recognition hardware in a low-noise environment has been developed for disabled persons capable of clear speech (Ding & Cooper, 2005).

The next, powered wheelchairs provide unique mobility for the disabled and elderly with motor impairments. Sometimes, the joystick is a useless manipulation tool because the severely disabled cannot operate it smoothly. Using natural voice commands, like ”move forward” or ”move left” relieves the user from precise motion control of the wheelchair. Voice activated powered wheelchair is required safety manipulation with high speech recognition accuracy because the accident can occur by a misrecognition. Although current speech recognition technology has reported high performance, it is not sufficient for safe voice-controlled powered wheelchair movement by inarticulate speech affected by severe...
cerebral palsy or quadriplegia, for instance. To cope with the pronunciation variation of inarticulate speech, we adopted a lexicon building approach based on Hidden Markov Model and data mining (Sadohara et al., 2005), in addition to acoustic-modeling-based speaker adaptation (Suk et al., 2005). We also developed noise-canceling methods, which reduce mechanical noise and environmental sounds for practical use on the street (Sasou et al., 2004). However, though our voice command system has improved recognition performance by various methods, the system requires a guarantee of safety for wheelchair users in two additional conditions.

- To move only in response to the disabled person’s own voice.
- To reject non-voice command input.

The first problem is to prevent operation of the wheelchair by unauthorized persons near the disabled user. A speaker verification method can be applied to solve this problem, but it is difficult to verify when using short word commands. Therefore, we are now developing a speaker position detection system using a microphone array (Jonson et al., 1993; Sasou & Kojima, 2006). The second problem is that a lot of other noise is input when the voice command system is being used. Also, a voice-activated control system must therefore reject noise and non-voice commands such as coughing and breathing, and spark-like mechanical noise in the preprocessing stage. A general rejection method has achieved a confidence measure using a likelihood ratio in a post-processing step. However, this confidence measure is hard to use as a non-command rejection method because of the inaccuracy of likelihood when speech recognition deals with unclear voice and non-voice sounds. Thus, a non-voice rejection algorithm that classifies Voice/Non-Voice (V/NV) in a Voice Activity Detection (VAD) step is useful for realizing a highly reliable voice-activated powered wheelchair system.

The chapter first presents the $F_0$ estimator and the non-voice rejection algorithm. Next, the inarticulate speech recognition is described in Section 3. In Section 4, we present a developed voice activated control system. And we evaluate the performance of our system in Section 5. Lastly, we offer our conclusions in Section 6.

2. Non-voice rejection using V/NV classification

The general VAD uses short time energy and/or ZCR for start and end point detection in a real-time voice command system with low complexity. However, VAD has a problem because various sounds are determined as voice sounds. Previous V/NV classification algorithms have generally adopted statistical analyses of $F_0$, the Zero-Crossing Rate (ZCR), and the energy of short-time segments. A method for voicing decision within a pitch-detection algorithm is presented in (Rouat et al., 1997). A combination of these methods, a cepstrum-based $F_0$ extractor, has been proposed (Ahmadi & Andreas, 1999). An auditory-based method for voicing decision within a pitch-tracking algorithm appears in (Mousset et al., 1996). For the purpose of non-voice rejection, we propose a V/NV classification using a reliable $F_0$ estimator.

2.1 YIN: fundamental frequency estimator

V/NV classification using $F_0$ information has been strongly tied to the problem of a pitch detection algorithm (PDA). A PDA can be formulated as an average magnitude difference function, average squared difference function, or similar autocorrelation methods in the time domain. In addition, cepstrum analysis is possible in the frequency domain by applying
the harmonic product spectrum algorithm. Among these $F_0$ extraction methods, we use the well known auto-correlation method based on YIN that has a number of modifications to reduce estimation errors (de Cheveigné, 2002). This method has the merit of not requiring fine tuning and uses fewer parameters. The name YIN (from “Yin” and “Yang” of oriental philosophy) alludes to the interplay between autocorrelation and the cancellation that it involves. The autocorrelation function of a discrete signal $x$, may be defined as

$$r_t(\tau) = \sum_{j=t+1}^{t+W} x_j x_{j+\tau}$$  \hspace{1cm} (1)

where $r_t(\tau)$ is the autocorrelation function of lag $\tau$ at time index $t$, and $W$ is the integration window size. YIN achieves a difference function instead of an autocorrelation function that is influenced in bias value.

$$d_t(\tau) = \sum_{j=t-\tau-W/2}^{t=\tau+W/2} (x_j - x_{j+\tau})^2$$  \hspace{1cm} (2)

Here, $d_t(\tau)$ is the difference function to search for the values of $\tau$ for which the function is zero. The window size shrinks with increasing values of $\tau$, resulting in the envelope of the function decreasing as a function of lag as illustrated in Fig. 1(a). The difference function must choose a minimum dip that is not zero-lag. However, setting the search range is difficult because of imperfect periodicity. To solve this problem, the YIN method replaces the difference function with the cumulative mean normalized difference function of Eq. (3). This function is illustrated in Fig. 1(b).

$$d'_t(\tau) = \begin{cases} 1, & \text{if } \tau = 0, \\ \frac{d_t(\tau)}{(1/\tau) \sum_{j=1}^\tau d_t(j)} & \text{otherwise} \end{cases}$$ \hspace{1cm} (3)

The cumulative mean normalized difference function not only reduces “too high” errors, but also eliminates the limit of the frequency search range, and no longer needs to avoid the zero-lag dip. One of the higher-order dips appears often in $F_0$ extraction, even when using

![Fig. 1. (a) Example of difference function (b) Cumulative mean normalized difference function at same waveform](www.intechopen.com)
the modified function in Eq. (3). This error is called the sub-harmonic or octave error. To reduce the sub-harmonic error, the YIN method finds the smallest value of $\tau$ that gives a minimum of $d_i(\tau)$ deeper than the threshold. Here, the threshold is decided by the value that adds a minimum of $d_i(\tau)$ to the absolute threshold $\alpha$ in Fig. 1 (b). Absolute threshold is possible because of the achieved normalized processing in the previous step. In the final step, $F_0$ is extracted through the parabolic interpolation and best local estimation process.

2.2 V/NV classification

The general V/NV classification algorithm participates in the processing of each short-time speech segment. However, classification of a whole input segment is more important in reliable speech recognition in which non-voice rejection is possible. For this classification, the proposed algorithm decides V/NV from the ratio of the reliable $F_0$ contour over the whole input interval.

The function value $d_i(\tau)$ defined by Eq. (3) is compared with the confidence threshold to decide the reliability of each $F_0$ frame. Here, the confidence threshold is selected such that the value is 0.05 to 0.2. Figures 2 and 3 depict examples of reliable $F_0$ contour extraction. A reliable $F_0$ contour using the cumulative mean normalized difference function is illustrated in Fig. 2 (b). When the confidence threshold of YIN-based $F_0$ is 0.1, only high reliability areas are selected, as illustrated in Fig. 2 (c).

Fig. 2. (a) Example of a voice waveform (b) Cumulative mean normalized difference function calculated from the waveform in (a) (c) Reliable F0 contour in which the confidence threshold is applied

The conventional VAD method using energy and/or ZCR is detected noise as well as voice in Fig. 3 (a). However, you can see that reliable $F_0$ appears on only three frames because of the applied confidence threshold 0.1 in Fig. 3 (c). Furthermore, we can prove the performance by the examining that detected frequency is the inner voice frequency area. For V/NV classification from the extracted $F_0$ contour, we then compute the ratio of frames with the reliable $F_0$ as follows.

$$d = \frac{1}{M} \sum_{i=1}^{M} P_{th}(i)$$

(4)

$$P_{th}(i) = \begin{cases} 
1 & \text{if } F_{\min} \leq F_{oth} \leq F_{\max} \\
0 & \text{otherwise}
\end{cases}$$

(5)
Here, $M$ indicates the total number of input frames, and $F_{\text{min}}=60 \text{Hz}$ and $F_{\text{max}}=800 \text{Hz}$ are experimentally chosen for a disabled person’s voice. Finally, an input segment is classified as voice if $d$ exceeds the $V/NV$ threshold value. The cepstrum-based algorithm can also be used as the confidence threshold for extraction of the $F_0$ contour as indicated in Fig. 4. However, the $F_0$ extraction performance of a cepstrum-based algorithm is inferior to YIN, and it is difficult to determine a suitable threshold in various environments.

3. Inarticulate speech recognition

The severely disabled person has the problem of pronouncing even simple voice commands. Specially, our system is required high performance of speech recognition when controlling a powered wheelchair, because recognition performance is related to the disabled person’s safety. Using the speech characteristics of each severely disabled person, the voice command input system needs to select words in which an utterance can be spoken easily and distinctly. Therefore, our system selected five of 12 word candidates using a test. However, as the disabled person has difficulty in speaking the command clearly, the utterance of “hi da ri” may be spoken as “hi hi hi da ri”, “i a ri” etc., in spite of the selected voice command. For this reason, a single-template dictionary is unable to recognize unusual speech.

A multi-template dictionary was generated through analysis of the speech patterns of the disabled to solve this problem. To generate a multi-template dictionary, the initial dictionary
Speech Recognition, Technologies and Applications

is prepared from the result of a phoneme-recognition experiment using a pre-recorded voice. The final dictionary is then generated by deleting unwanted candidates through a repetitive word-recognition experiment. The generated multi-template dictionary was comprised of the 27 templates of the “hidari” utterance, 15 templates for “migi,” 13 templates for “mae,” 4 templates for “koutai,” and 5 templates for “ah.”

Table 1. Implemented set and multiple dictionaries for inarticulate speech recognition

Since speech recognition systems are known to demonstrate different results from reading speech and spontaneous speech, it is important for evaluation and modeling of voice command system. To obtain a sample of spontaneous speech affected by disability, which contains specific personal variations, we developed a voice operated toy robot and a graphical simulation demo system that uses the same recognition task such as in powered wheelchair operation.

For analysis of the input devices, each input device achieved speech detection through each recognition engine at the same time. Currently, we have collected more than 3000 unclear samples of speech affected by disability, using four types of microphones: headset(Audio-technica: AT810X), Bone conduction(Sony: ECM-TL1), Pin(PAVEC: MC-105), Bluetooth (Sonorix: OBH-0100). Transmission capacity of bluetooth microphone is limited by an 8 KHz sampling rate. Table 2 lists the recorded speech data used for the experimental evaluation.

For the headset type, 579 inputs are collected. There are also 426 voice commands, 65 various noises, 76 other utterances that are not commands, and utterances of 12 another people. Therefore, V/NV classification is needed to satisfy voice activated powered wheelchair control requirements while maintaining high speech recognition accuracy.

#### 4. Voice activated control system

The voice activated home appliances control system diagram is shown in Figure 6. In the diagram, speech input device is can be use not only headset but also mobile telephone via Skype Voice of IP (VOIP) module. At First, the microphone captures the speech signal. The incoming audio stream is then segmented for recognition using the VAD module. The stream is transmitted from speech interface to the recognition engine where the recognition procedure is carried out. Our recognition engine employed a Julian decoder (Lee at al., 2001) with mel frequency cepstral coefficient and adapted a speaker-dependent acoustic model. Finally the recognition result is executed when results are satisfied with voice using V/NV classification module.

By using the result of speech recognition for infrared remote control, system can be remote control powered wheelchair and home appliances including TV, radio, VCD/DVD player, lights, and fan. System is also offers hand-free management of telephone calls and direct calling to family through one voice command. Software is designed and developed under the visual studio platform and using visual C++ programming, which can be installed and run in Ultra Mobile PC (UMPC) under operating system of embedded windows.

![Fig. 6. Voice activated home appliance control system design](image-url)
A voice controlled Graphic User Interface (GUI) is carefully designed for disabled person in Fig. 7. Click of the icon on the user’s screen or voice command directly correspond to environmental commands (switching on the lamps, starting the Radio, calling the facilitator).

The developed system consists of a headset, a Pentium M 1.2GHz UMPC, infrared transmitter for long distance transmission and a wheelchair controller, as depicted in Fig. 8. Also, wireless microphone or mobile phone can be used instead of wire headsets for user convenience.

The voice commands to control wheelchair direction are not easy when use the minimum number of commands. So, our system use the state transition diagram for more free movement of voice activated powered wheelchair, as shown in Fig. 9.
5. Experiment results

To evaluate the performance of our proposed method, we conducted V/NV classification experiments using the 1567 voice commands and 447 noises and employing YIN-based and cepstrum-based algorithms. The sampling frequency was 16kHz, the window size was 25ms, and the frame shift was 8ms.

Figure 10 depicts the V/NV classification performance and plots the recall-precision curves according to an individual confidence threshold. The results indicate that the YIN-based algorithm is superior to the cepstrum-based algorithm. When the confidence threshold of YIN is 0.08, the V/NV classification provides the best results with 0.97 and 0.99 rates for recall and precision. In other words, when the lowest threshold was selected for voice detection at a precision rate of 1, the miss-error rate of noise was only 4.9%.

Table 3 lists the best confidence threshold of each microphone with the best recall precision. When YIN uses the $F_0$ extraction method, the confidence threshold is stable at about 0.08.
Although the cepstrum algorithm can use the $F_0$ extraction method, it is difficult to decide on a suitable confidence threshold in each microphone environment.

Table 3. Confidence threshold analysis of four types of microphones with the best recall precision

A recognition experiment was performed in order to confirm the validity of the multi-candidate recognition dictionary and the adapted acoustic model for the basic performance of a voice-activated system. The recognition experiment used 2211 data elements recorded at an athletic meeting and outdoors with a noise background to evaluate the effectiveness of the proposed multi-template dictionary and adapted acoustic model. Ninety-six utterances were used for adaptation of the acoustic model, and the remaining 1334 utterances were used for evaluation.

Table 4. Speech recognition accuracy with 2000-state HMnet model

The speaker-independent, 2000-state 16-mixture HMnet model was evaluated as the baseline. An average recognition rate of 78.6 was achieved, although there were five words in the dictionary because it did not consider the speech characteristics and variations of disabled persons. The average recognition rate was improved to 93.8% by applying the multi-template dictionary. The acoustic model that performed MAP adaptation achieved an average recognition rate of 98.6%. The average recognition rate was improved to 99.5% by applying the multi-template dictionary with the adapted acoustic model.

6. Conclusion

This chapter presented home appliances control system for independent life of the severely disabled person. In particular, the developed system can be operated by inarticulate speech and a non-voice rejection method for reliable VAD in a real environment with extraneous sounds such as coughing and breathing. The method classifies V/NV from the ratio of reliable $F_0$ contour over the whole input interval. We adopted the $F_0$ extraction method where YIN has the best performance among conventional methods. Our experiment results indicate that the false alarm rate is 4.9% with no miss-errors in which voice is determined to
be non-voice. And the average recognition rate was improved to 99.5% by applying the multi-template dictionary with the adapted acoustic model. Therefore, the speaker dependent acoustic model, dictionary and non-voice rejection algorithm can be helpful for realizing a highly reliable wheelchair control system.

7. Acknowledgement

I would like to thank K. Sakaue for his invaluable comments, and A. Sasou and other Speech Processing Group members for their contribution to this work. I would also like to thank M. Suwa, T. Inoue and other members of Research Institute, National Rehabilitation Center for Persons with Disabilities for their support for the experiments. This work was supported by KAKENHI (Grant-in-Aid for JSIPS Fellows).

8. References

Chapters in the first part of the book cover all the essential speech processing techniques for building robust, automatic speech recognition systems: the representation for speech signals and the methods for speech-features extraction, acoustic and language modeling, efficient algorithms for searching the hypothesis space, and multimodal approaches to speech recognition. The last part of the book is devoted to other speech processing applications that can use the information from automatic speech recognition for speaker identification and tracking, for prosody modeling in emotion-detection systems and in other speech processing applications that are able to operate in real-world environments, like mobile communication services and smart homes.
