Testicular Germ Cell Tumours
– A European and UK Perspective

Nikhil Vasdev and Andrew C. Thorpe

Department of Urology
Freeman Hospital
Newcastle upon Tyne
United Kingdom

1. Introduction

Testicular Germ Cell tumours (TGCTs) account for between 1% and 1.5% of male neoplasms and 5% of urological tumours in general, with 3-10 new cases occurring per 100,000 males/per year in Western society (1-3). Testicular germ cell tumours (TGCTs) are the most frequent solid tumour of Caucasian adolescents and young adult males and are a diverse group of neoplasms that can also present in extragonadal sites. Within Europe, there has been a general increase in the incidence of TGCTs noted initially in the 1970s and 1980s (4). Over recent years the incidence of TGCTs has risen markedly, making it imperative to understand how and why these tumours arise.

In this book chapter we present the incidence and clinical presentation, classification, epidemiology and aetiology, molecular developments, tumour markers, staging, management strategies including the role of chemotherapy, radiotherapy and Retroperitoneal lymph node dissection (RPLND) and follow up protocol followed in the United Kingdom (UK) and Europe as per the 2011 European Association of Urology (EAU) guidelines.

2. Incidence and clinical presentation

Testicular Germ Cell tumours (TGCTs) are broadly divided into Seminomas, which resemble primordial germ cells (PGCs) and Non-Seminoma, which are either undifferentiated (embryonal carcinoma) or differentiated (exhibiting a degree of embryonic (teratoma) or extra-embryonic (yolk sac choriocarcinoma) pattern (5). The commonest age range of presentation of TGCTs is between 20-45 years. Patients rarely tend to be younger than 15 years or older than 60 years. Based on the type of TGSTs, Seminomas typically arise later in life, with a mean age at presentation of 35 years of age compared with 25 years of age for non-seminomas. Although these morphologies and differences in age at presentation could suggest underlying differences between seminomas and non-seminomas, several lines of evidence support a common underlying pathogenesis. Approximately 15% of TGCTs are mixed tumours that contain both seminoma and non-seminoma elements (6).
The commonest presentation of TGCTs is a painless unilateral mass in the scrotum when the patient feels the mass itself. In other situations the patient has an incidental mass diagnosed when presenting with other symptoms of a concomitant testicular pathology such as epididymitis. It is interesting to note that 10% of patients presenting with epididymitis present can present with a TGCTs (1, 2). Another common symptom of presentation is testicular pain (1) seen in up to 20% of patient with TGCTs. In certain cases up to 27% of patients have local pain which could be attributed to a degree of local invasion (1). Up to 1-2% of TGCTs present bilaterally. Paraneoplastic symptoms such as gynaecomastia can be seen in up to 7% of patients at initial presentation. Additional symptoms include lower back pain and loin pain (1, 2).

When a patient presents with a testicular mass it is extremely important to elicit a detailed history which includes duration of symptoms, whether the mass is painful or painless, change in size of mass, sexual history, concomitant lower urinary tract symptoms, previous history of surgery, infertility or mumps and family history of testicular cancer. There is evidence to suggest that delay in presentation is more of a problem than delay in referral and this has prompted some authors to suggest that a public education campaign might be helpful (7,8).

The radiological investigation of choice for testicular cancer is an ultrasound throughout Europe. The main advantage lies with the fact that an ultrasound is non radiation exposure scan and is relatively inexpensive. The current sensitivity and specificity of an ultrasound of testis is 100% (9). In patients with an equivocal diagnosis a Magnetic resonance imaging (MRI) offers a sensitivity of 100% and a specificity of 95-100% (10), but its high cost does not justify its use for diagnosis.

3. Classification

As the 2011 European Association of Urology (EAU) guidelines testicular cancer is classified according to the 2004 World health organization (WHO) guidelines (11). From the perspective of this book chapter we will confine our discussion to Testicular Germ Cell Tumours only.

1. Germ cell tumours
   - Intratubular germ cell neoplasia, unclassified type (IGCNU)
   - Seminoma (including cases with syncytiotrophoblastic cells)
   - Spermatocytic seminoma (mention if there is sarcomatous component)
   - Embryonal carcinoma
   - Yolk sac tumour
   - Choriocarcinoma
   - Teratoma (mature, immature, with malignant component)
   - Tumours with more than one histological type (specify percentage of individual components)

2. Sex cord/gonadal stromal tumours
   - Leydig cell tumour
   - Malignant Leydig cell tumour
   - Sertoli cell tumour
     - lipid-rich variant
     - sclerosing
     - large cell calcifying
Testicular Germ Cell Tumours – A European and UK Perspective

- Malignant Sertoli cell tumour
- Granulosa cell tumour
  - adult type
  - juvenile type
- Thecoma/fibroma group of tumours
- Other sex cord/gonadal stromal tumours
  - incompletely differentiated
  - mixed
- Tumours containing germ cell and sex cord/gonadal stromal (gonadoblastoma)

3. Miscellaneous non-specific stromal tumours
- Ovarian epithelial tumours
- Tumours of the collecting ducts and rete testis
- Tumours (benign and malignant) of non-specific stroma.

4. Epidemiology and aetiology

The Epidemiology and Aetiology of TGCTs has evolved over the past two decades.

4.1 Age

In the paediatric population i.e., patients ≤ 16 years, the commonest form of Testicular Tumours are Mature teratomas, rhabdomyosarcoma, epidermoid cyst, yolk sac and germ cell tumours. The commonest age group of patients affected with TGCTs is between 20-45 years. Teratomas are common between the age of 20-35 years while seminomas are more common between the ages of 25-45 years. In men above the age of 60 years the commonest tumour is a lymphoma.

4.2 Cryptorchidism

When patients present with cryptorchidism, there is risk of development of testicular tumour on both the effected side and contralateral side in the long term. The risk of TGCT in the Undescended Testis (UDT) is increased by 4 - 13 , with up to 7-10% of Testicular Cancers developing in UDT (12). There is a 5-10% risk of developing testicular cancer in the contralateral testis in those with a history of UDT (13). Premalignant changes within the UDT commence by the age of 3 years. However, an early orchidopexy does not completely eliminate the risk of developing testicular cancer in the long term.

4.3 Intratubular Germ Cell Neoplasia (IGCNU)

Intratubular germ cell neoplasia (IGCNU) is also known as carcinoma in situ (CIS) of the testis. The incidence of IGCNU in the overall population is 0.9%. Intratubular germ cell neoplasia is defined as a pre-invasive testicular germ cell lesion and is now believed an important precursor of TGCTs. The only TGCT not associated with IGCNU is a spermatocytic seminoma. When IGNU is present, the probability of progression to TGCTs increases by 50% over a duration of 5 years. At 7 years, the cumulative probability of developing a TGCTs increased to 70% (14).

The incidence of IGCNU is the contralateral testis in patients with TGCTs is 5-9%. The incidence however rises to 34% when the primary TGCTs has been diagnosed before the age
of 40 years and the testicular volume is less than 12 ml. In both the above mentioned scenarios, the EAU guidelines recommends a biopsy of the contralateral testis. It is important to note that the presence of IGCNU in the ipsilateral testis does not have any bearing on the patients overall prognosis. Risk factors for IGCNU include cryptorchidism (UDT), extra-gonadal germ cell tumour, previous or contralateral TGCT (5%), atrophic testicle with a volume of less than 12 ml, early age of diagnosis of TGCTs i.e., ≤ 40 years, 45XO karyotype, Klinefelter's syndrome and infertility. Once IGCNU is diagnosed, local radiotherapy is the treatment of choice in solitary testis. Because this may produce infertility, the patient must be carefully counselled before treatment commences.

4.4 Maternal oestrogen exposure

Maternal Oestrogen Exposure (MOE) increases during pregnancy and hence increases the risk of cryptorchidism and TGCT in the male offspring. The MOE with diethylstilboestrol increases the risk of TGCTs by a relative risk of 2.8 - 5.3% (13).

4.5 Subfertility

A history of subfertility and poor quality semen analysis increases the risk of testicular cancer by up to 1.6 times and from the Surveillance Epidemiology and End Results database by 20 times (14).

4.6 Family history

Familial history of testicular tumours among first-grade relatives (father/brothers) has been associated with isochromosome of the short arm of chromosome 12 – i(12p) (15).

4.7 Additional factors

Additional factors such as tallness, previous history of Marijuana exposure, vasectomy, trauma, mumps and Human Immunodeficiency Virus (HIV) infection continue to be evaluated (13-15).

5. Genetic and cellular markers

Current research has identified deregulation in the pluripotent programme of fetal germ cells (identified by specific markers such as M2A, C-KIT and OCT4/NANOG) is probably responsible for the development of IGCNU and germ cell neoplasia. There is overlap in the development to seminoma and embryonal carcinoma as shown by genomewide expression analysis and detection of alpha-fetoprotein (AFP) mRNA in some atypical seminoma (16,17). Continued genome wide screening studies and gene expression analysis data suggest testis cancer specific gene mutations on chromosomes 4, 5, 6 and 12 (namely expressing SPRY4, kit-Ligand and Synaptopodin) (18-20). Intratubular germ cell neoplasia shows alterations in the p53 in up to 66% of cases.

Newer developments continue to be made with regards to further molecular profiling of TGCTs. The current molecular developments include characterization of newer markers such as MAGEC2 expression. This newer marker allows a reliable distinction of seminoma
from embryonal carcinomas. Therefore, MAGEC2 represents an additional tool for the differential diagnosis of testicular germ cell tumours (21).

6. Serum markers for TGCTs

For the successful management of TGCTs it is crucial to understand the molecular details, half lives and clinical applications of testicular tumour markers. In clinical practice with Europe and the UK, the three common tumour markers used include Alpha-fetoprotein (AFP), β- human chorionic gonadotrophin (β-HCG) and lactate dehydrogenase (LDH). All testicular tumour markers contribute to the patients diagnosis and more importantly to the final prognosis. When a patient is diagnosed with a TGCTs, tumour markers will be elevated in 51% of cases (22).

Alpha-fetoprotein (AFP) is expressed by trophoblastic elements within 50-70% of non-seminomatous germ cell tumour (NSGCT) and yolk sac tumours. In patients with an elevated AFP with Seminoma alone, this raises the suspicion of the presence of Non-seminomatous elements. The half life of AFP is 5-7 days and the normal serum levels are <10 ng/ml. β- human chorionic gonadotrophin (β-HCG) is produced by syntiotrophoblast elements. In patients with choriocarcinomas, β-HCG is elevated in 100% of cases. From the perspective of other TGCTs, β-HCG is elevated in 40% of cases of NSGCT and 10% of Seminomas. The half life of β-HCG is 24-36 hours and normal serum levels are < 5mIU/ml. About 90% of non-seminomatous tumours present with a rise in one or two of the markers.

Lactate dehydrogenase (LDH) is a less specific marker and is an ubiquitous enzyme elevated in serum from various causes, therefore is less specific. It is elevated in 10-20% of seminomas but may be elevated in 80% of patients with advanced testicular cancer (23). Other markers studied include Placental alkaline phosphatase (PLAP), which may be of value in monitoring patients with pure seminoma. placental alkaline phosphatase (PLAP) is a foetal enzyme and may be falsely elevated in smokers. Cytogenetic and molecular markers are available in specific centres, but at present only contribute to research studies. Measurement of serum AFP, hCG and LDH is mandatory, while that of PLAP is optional.

Testicular tumour serum markers are normally measured when a patient presents with a TGCT clinically. In Europe the Testicular tumour markers are measured 1-2 weeks following radical orchidectomy. The testicular tumour markers play an important role in assessing response to treatment and follow up. The presence of normal testicular tumour markers prior to orchidectomy does not normally exclude the presence of micrometastatic disease. However, the persistence of testicular tumour markers following post radical inguinal orchidectomy may occur in patients with hepatic dysfunction, hypogonadotropism and most importantly in metastatic disease.

It is also important to note that other malignancies may cause an elevation of testicular tumour markers. Liver, pancreatic, gastric and lung malignancies may cause an elevated AFP level. Pancreatic, liver, gastric, lung, breast, kidney and bladder cancer may cause an elevated β-HCG level. Prior to commencing chemotherapy all tumour markers must be performed to classify patients according to the International Germ Cell Cancer Collaborative Group (IGCCC) risk classification.
7. Staging

Once a patient is diagnosed with a TGCTs the patient is staged with a thorough history and clinical examination. In the patient’s history it is important to ask the following questions with regards to the testicular lump. The crucial points in the history include the duration of symptoms, whether the lump is painful or painless, change in size of the lump, previous surgical history of UDT, sexual history, history of lower urinary tract symptoms and family history. Clinical examination includes assessment of supraclavicular lymph node, chest examination and abdominal examination for inguinal lymph nodes. At this stage a full set of Testicular tumour markers is performed which includes serum AFP, β-hCG and LDH is mandatory, while that of PLAP is optional. In cases of disseminated disease and life-threatening metastases, it is current practice to start with up-front chemotherapy, and orchidectomy may be delayed until clinical stabilisation has occurred.

In patients with a suspected testicular mass a radical inguinal orchidectomy is performed. The main principal of this procedure lies with exteriorisation of the testicle within its tunics. Prior to mobilization of the testis and cord, the cord is isolated and clamped to allow control of the draining lymphatics in order to minimize spillage and metastatic spread. If the diagnosis is not clear, a testicular biopsy (an enucleation of the intraparenchymal tumour) is taken for frozen section histological examination.

When the testicle is sent for pathological analysis, the EAU 2011 guidelines recommend a mandatory assessment of the specimen for the following features as these features further help prognosticate the patients’ outcome. The features include:

1. Macroscopic features: side, testis size, maximum tumour size, and macroscopic features of epididymis, spermatic cord, and tunica vaginalis.
2. Sampling: a 1 cm² section for every centimetre of maximum tumour diameter, including normal macroscopic parenchyma (if present), albuginea and epididymis, with selection of suspected areas. At least one proximal and one distal section of spermatic cord plus any suspected area.
3. Microscopic features and diagnosis: histological type (specify individual components and estimate amount as percentage) according to WHO 2004 (11):
   a. Presence or absence of peri-tumoural venous and/or lymphatic invasion;
   b. Presence or absence of albuginea, tunica vaginalis, rete testis, epididymis or spermatic cord invasion;
   c. Presence or absence of intratubular germ cell neoplasia (IGCNU) in non-tumour parenchyma intratubular germ cell neoplasia.
   d. pT category according to Tumour Node Metastasis (TNM) 2009.
   e. Immunohistochemical studies: in seminoma and mixed germ cell tumour, AFP and hCG.

Following radical inguinal orchidectomy, the main aim of clinical staging is to determine whether the patient has metastatic or occult disease at the time of presentation. The investigations of choice to determine the above and accurately stage the TGCTs at presentation include the post-orchidectomy half-life kinetics of serum tumour markers; the status of retroperitoneal and supraclavicular lymph nodes, and the liver; the presence or absence of mediastinal nodal involvement and lung metastases; the status of brain and bone, if any suspicious symptoms are present. At this point all patients must have a serial
testicular tumour markers measured and a thorough assessment of the retroperitoneum staging CT of the Chest, Abdomen and Pelvis. Retroperitoneal and mediastinal lymph nodes are best assessed by means of a CT scan. The supraclavicular nodes are best assessed by physical examination.

Hence, in Europe and the UK all patients with newly diagnosed TGCTs have the following investigations performed:-

a. Serum testicular tumour markers (AFP, β-hCG and LDH)
b. CT - Chest, Abdomen and Pelvis
c. Ultrasound Testis (Bilateral)

A bone scan is organized in patients with suspected advances metastatic disease. A Brain CT is organized in patients In case of symptoms and patients with metastatic disease with multiple lung metastases and high beta-hCG levels. In some centre a detailed hormonal profile (Serum Testosterone, FSH, LH) and semen analysis is performed.

In all patients undergoing a radical inguinal orchidectomy it is important to counsel patients on the options of sperm banking and insertion of a testicular prosthesis. The 2011 EAU guidelines recommend cryopreservation of sperm prior to orchidectomy. This should be specifically offered in all patients with a history of Subfertility and atropic contralateral testis. In patients keen to pursue the insertion of a testicular prosthesis at the time of an inguinal orchidectomy, the risk of a possible delay to chemotherapy secondary to prosthesis related infection (0.6-2%) (24) must be highlighted.

7.1 Staging and prognostic classifications

The staging system recommended in these guidelines is the 2009 TNM of the International Union Against Cancer (UICC) (25) include the following parameters :

a. Determination of the anatomical extent of disease
b. Assessment of serum tumour markers, including nadir values of hCG, AFP and LDH after orchidectomy (S category)
c. Clear definition of regional nodes
d. N-category modifications related to node size

The 2009 TNM of the International Union Against Cancer (UICC) is summarized in Table 1.

1. pT Primary tumour
   pTX Primary tumour cannot be assessed
   pT0 No evidence of primary tumour (e.g. histological scar in testis)
   pTis Intratubular germ cell neoplasia (testicular intraepithelial neoplasia)
   pT1 Tumour limited to testis and epididymis without vascular/lymphatic invasion: tumour may invade tunica albuginea but not tunica vaginalis
   pT2 Tumour limited to testis and epididymis with vascular/lymphatic invasion, or tumour extending through tunica albuginea with involvement of tunica vaginalis
   pT3 Tumour invades spermatic cord with or without vascular/lymphatic invasion
2. Regional lymph nodes clinical

NX Regional lymph nodes cannot be assessed

N0 No regional lymph node metastasis

N1 Metastasis with a lymph node mass 2 cm or less in greatest dimension or multiple lymph nodes, none more than 2 cm in greatest dimension

N2 Metastasis with a lymph node mass more than 2 cm but not more than 5 cm in greatest dimension, or multiple lymph nodes, any one mass more than 2 cm but not more than 5 cm in greatest dimension

N3 Metastasis with a lymph node mass more than 5 cm in greatest dimension

3. pN Pathological

pNX Regional lymph nodes cannot be assessed

pN0 No regional lymph node metastasis

pN1 Metastasis with a lymph node mass 2 cm or less in greatest dimension and 5 or fewer positive nodes, none more than 2 cm in greatest dimension

pN2 Metastasis with a lymph node mass more than 2 cm but not more than 5 cm in greatest dimension; or more than 5 nodes positive, none more than 5 cm; or evidence of extranodal extension of tumour

pN3 Metastasis with a lymph node mass more than 5 cm in greatest dimension

4. M Distant metastasis

MX Distant metastasis cannot be assessed

M0 No distant metastasis

M1 Distant metastasis

M1a Non-regional lymph node(s) or lung

M1b Other sites

5. S Serum tumour markers

Sx Serum marker studies not available or not performed

S0 Serum marker study levels within normal limits

Table 2. The AJCC staging groupings of Testicular Tumours

8. Management

Within Europe and the UK the management of TGCTs differs mainly for the indications of Retroperitoneal Lymph Node Dissection (RPLND) in both Stage I and Stage II disease. We classify the management of TGCTs as followed in Europe and the UK based on whether the tumour is a Seminoma or Non-Seminoma.

8.1 Management of Seminoma

Of all Seminomas diagnosed, 75% are confined to the testicle itself at the time of clinical presentation and a complete cure is thus achieved with a thorough radical inguinal orchidectomy. In up to 10-15% of patients metastasis is present at the time of diagnosis with a further 5-10% of patients having more advanced disease.

In patients with Non-metastatic Stage I seminoma (T1N0M0S0-1) the risk of subsequent para-aortic lymph node relapse is 20%. Adjuvant therapy with either chemotherapy or radiotherapy reduces the risk of recurrence to <1%.

8.1.1 Management of stage I Seminoma

The options in a patient with Stage 1 Seminoma include surveillance, adjuvant chemotherapy or adjuvant radiotherapy. The option of surveillance is indicated as 75% of Seminoma are cured following a radical inguinal orchidectomy. In a large study of 1500 patients (28) indicated the overall rate of retroperitoneal disease relapse to be 16.8%. It is important to characterize patients with high risk Stage I Seminoma based on initial pathology. The 2 most important factors associated with poor prognosis includes the presence of rete-testis invasion and tumours size of ≥ 4 cm. The overall cancer-specific survival rate reported with surveillance performed by experienced centres is 97-100% for seminoma stage I (29-31). The main drawback of surveillance is the need for more intensive
follow-up, especially with repeated imaging examinations of the retroperitoneal lymph nodes, for at least 5 years after orchidectomy.

Table 3. Prognostic-based staging system for metastatic germ cell cancer (International Germ Cell Cancer Collaborative Group).

Patients with Stage I Seminoma can also be given adjuvant chemotherapy with one cycle of Carboplatin (33). An alternative to surveillance or chemotherapy in patients with radiotherapy (34).

Within Europe and the UK, a RPLND is not recommended in patients with Stage 1 Seminoma. In prospective, non-randomised study comparing radiotherapy and RPLND in stage I seminoma, there was a trend towards a higher incidence of retroperitoneal relapses (9.5%) after RPLND as primary treatment (35).

In summary, it is important to stratify patients with Stage 1 Seminoma into high risk based on the presence of rete testis invasion and tumour volume of ≥ 4 cm. In these patients the
option of adjuvant chemotherapy and radiotherapy is justifiable. In patients without rete
testis invasion or in whom the testicular tumour volume is ≤ 4 cm the option of surveillance
alone is recommended.

8.1.2 Management of stage II Seminoma

The options in a patient with Stage II Seminoma is radiotherapy. However, chemotherapy is
an alternative management strategy.

8.2 Management of Non-Seminoma

In patients with Non-Seminomas, 30% with Stage I disease will have subclinical metastases
and will relapse if surveillance alone is applied following orchidectomy. Within this groups
of patients the options of treatment include surveillance, chemotherapy and RPLND. It is
important to stratify Non-Seminomas into high risk based tumours depending on the
following parameters which include the presence of Vascular/lymphatic in or peri-
tumoural invasion, proliferation rate > 70% or percentage of embryonal carcinoma > 50%.

8.2.1 Management of stage I Non-Seminoma

In patients on surveillance, the incidence of relapse is 30% (36). When a patient relapses
about 35% have normal levels of serum tumour markers at relapse and approximately 60% of
relapses are within the retroperitoneum. Upto 11% of relapsing patients have large-
volume recurrent disease at representation. Based on the above, the option of surveillance
should be offered to a compliant patient who will agree for very regular and close follow up.

The commonest option of management of patients within Europe and the UK with Stage I
Non-Seminoma is chemotherapy. The current recommendation is two courses of
chemotherapy with cisplatin, etoposide and bleomycin (PEB) as primary treatment for high-
risk patients (having about 50% risk of relapse). Patient receiving adjuvant chemotherapy
must be monitored closely as there is a risk of slow-growing retroperitoneal teratomas after
primary chemotherapy.

A Nerve sparing / template based RPLND can also be offered to patient who are not keen to
receive chemotherapy. It is interesting to note that about 30% of patients are diagnosed to
have a retroperitoneal lymph node metastases corresponding to pathological stage II (PS2)
disease. In patients with no retroperitoneal metastases found at RPLND (PS1),
approximately 10% of the PS1 patients relapse at distant sites. Within the UK, RPLND is
normally indicated in post chemotherapy recurrence.

As with seminomas a further risk adaptive strategy can be adapted for Non-Seminomas. If the
risk-adapted policy is applied, patients with vascular invasion are recommended to undergo
adjuvant chemotherapy with two cycles of PEB, and patients without vascular invasion are
recommended to undergo surveillance. In summary patients with CS1A (pT1, no vascular
invasion), low risk Stage I Non Seminoma can be offered the option of surveillance. If patients
are not willing (or suitable) to undergo surveillance, adjuvant chemotherapy or nerve-sparing
RPLND are alternative treatment options. If RPLND reveals PN+ (nodal involvement) disease,
chemotherapy with two courses of PEB should be considered. Patients with Stage I Non-
Seminoma CS1B (pT2-pT4) high risk disease receive either primary chemotherapy with two
courses of PEB or Surveillance or nerve-sparing RPLND in high-risk patients remain options for those not willing to undergo adjuvant chemotherapy.

**8.2.2 Management of stage II Non-Seminoma**

In patients with Stage II Non-Seminoma with normal testicular tumour markers can be managed with primary RPLND or surveillance. In patients with elevated tumour markers primary chemotherapy is recommended. When surveillance is commenced for a lesion the lesion can either regress, resolve or progress with either a rise or no rise in concomitant testicular markers.

When a lesion regresses in the absence of rising tumour markers it is unlikely to be a malignancy. A lesion growing represents either a teratoma or a well differentiated tumour in the absence of rising testicular tumour markers. In this situation a RPLND should be performed by an experienced surgeon. Patients with a growing lesion and a concomitant increase in tumour markers AFP or beta-hCG should not undergo surgery. These patients require chemotherapy with PEB according to the treatment algorithm for patients with metastatic disease and IGCCCG. Patients who are unwilling to commence primary chemotherapy have an option of a nerve-sparing RPLND with adjuvant chemotherapy (two cycles of PEB) in case of metastatic disease (pII A/B).

**9. Follow up**

Follow-up care with an oncologist, urologist or both, is vital for the patient with testicular cancer. Regular assessments are required to monitor tumour markers in the blood, chest X-rays, CT scans of the abdomen and a full medical examination with psychological support. This process may continue for several years and may vary depending on the type and stage of the disease.

**10. Conclusion**

In conclusion the management of TGCTs within the UK and Europe is based on the individuals management (surveillance, chemotherapy or radiotherapy) which has to be balanced according to clinical features and the risk of short-term and long-term toxic effects. Although cure rates for Stage 1 disease are high, there continues to be significant morbidity due to chemotherapy, RPLND and Radiotherapy for concomitant additional treatment. We recommend individualizing patient treatment using a Multidisciplinary team approach using the latest regional, national and international guidelines and developments.

12. References

The book aims to provide an overview of current knowledge regarding germ cell tumors. It deals with the clinical presentations, treatment modalities, the biology and genetics of germ cell tumors in children and adults. Most chapters are focused on testicular germ cell tumors whose incidence has been increasing in young males. Included are reviews on the pathogenesis, risk factors, diagnosis and treatment regimens applied to precursor, pre-invasive lesions as well as to seminomatous and non-seminomatous germ cell tumors of the testes. In addition, a review is included on the diagnosis and current management options for intracranial germ cell tumors in children. Authors have also contributed articles on the genetics and epigenetics of germ cell tumor development in humans and in the mouse model system. This book will be of interest to scientists, physicians and lay readers wishing to review recent developments in the field of germ cell cancers.
