1. Introduction

One of the 20th century’s significant achievements is a discovery of azithromycin (1) and its development to commercial product for effective treatment of various infective diseases. Owing to its exceptional therapeutic and biopharmaceutical properties, it has come to be one of the most successful antibiotics worldwide. For the discovery of azithromycin, in addition to receiving numerous awards, in the year 2000, PLIVA’s scientists Slobodan Djokic and Gabrijela Kobrehel together with the representatives from the US-based Pfizer, Gene Michael Bright and Arthur E. Girard, (Anonymous, 2000) were granted the honourable titles of "Heroes of Chemistry" by the American Chemical Society (ACS), a non-profit association of American chemists and chemical engineers, and the largest association of scientists in the world. This prestigious award is taken to be also recognition of the achievement of PLIVA’s entire team working on azithromycin. The success of azithromycin has positioned PLIVA among the few pharmaceutical companies in the world that have developed their own blockbuster drug, and has entitled Croatia to join a small group of nations that have developed a new antibiotic.

Nowadays, on the occasion of the 30th anniversary of azithromycin’s invention (1981-2011) an increasing prevalence of antibiotic-resistant pathogens suggests that we deeply entered into a “Post-Antimicrobial Era” (Cohen 1992; Travis 1994; Kirst 1996b). Investment in newer anti-infective platforms is essential and urgent in order to achieve a significant progress in our understanding of bacterial resistance and new approaches how to control it.
Macrolides as polyketide class of natural products have a long history as effective therapeutic agents for treating infectious diseases (Schönfeld & Kirst, 2002; G.T. Hansen et al., 2002; T. Kaneko et al., 2006). The popularity of this class of antibiotics, inhibiting bacterial protein synthesis by interfering with ribosome function, is largely due to their spectrum of activity and their relative safety. They are still in the centre of interest of many research groups from academic institutions and pharmaceutical companies and much effort is directed toward the discovery of new macrolide antibiotics by chemical modification of the existing classes of natural derivatives (Sunazuka et al. 2002; Pal 2006). Antibacterial macrolides have attracted considerable attention for two main reasons: (a) the emergence of atypical and/or new pathogens and extensive clinical application of these antibiotics had resulted in an increasing emergence of bacterial resistance, especially among macrolide-resistant *Streptococcus pneumoniae*, *Streptococcus pyogenes*, and *Staphylococcus aureus* strains, and, therefore, the development of alternative antibacterial agents became essential; (b) macrolide derivatives, especially 14- and 15-membered classes, have also become interesting for treating important chronic diseases, that is, asthma, chronic sinusitis, diffuse panbronchiolitis, cystic fibrosis (Čulić, 2001; Labro, 2000; Labro, 2004), bronchiolitis obliterans syndrome (BOS) (Vanaudenaerde et al., 2008; Culic et al., 2006), etc. Some macrolides proved active in treatment of malaria (Andersen et al., 1994; Kuschner et al., 1994; Andersen et al., 1995; Ohrt et al., 2002; Sidhu et al., 2007) and cancer (Romano et al., 2004; Oyelere et al. 2009; Mwakwari et al. 2010; Bao et al., 2010), showed antiparasitic activity (Lee et al. 2011) or act as motilides, *ie.* macrolides with gastrointestinal motor stimulating activity (Takanashi et al. 2009).

Following this trend, the chemists from PLIVA Pharmaceuticals (Zagreb, Croatia) discovered in 1980 the famous azithromycin molecule, 1 (Fig. 1), characterized by unique 15-membered macrolide ring system, having a basic methylamino group inserted into the erythromycin aglycone (Kobrehel & Djokić 1982; Kobrehel et al., 1982; Kobrehel & Djokić, 1985; Djokić et al. 1986; Djokić et al. 1987; Djokić et al. 1988). Soon after the publication of PLIVA’s Belgian azithromycin patent, researchers at Pfizer (Groton, USA) prepared azithromycin independently, as the results of their own research program (Bright 1984).

Azithromycin was, beside clarithromycin, the leader of the second-generation of macrolides, the first representative of new series of macrolides termed “azalides” (Schönfeld & Mutak 2002; Mutak 2007), and today the golden standard for macrolide antibiotics (Spaventi 2002).

Azithromycin has broad spectrum of activity against all relevant bacteria causing respiratory tract infections, including *Haemophilus influenzae* and *Moraxella catarrhalis* (Mutak, 2007). It also possesses excellent safety and tolerability profiles and is widely prescribed for the treatment of upper and lower respiratory tract infections (Kirst, 1996a; Girard et al., 1987; Schönwald et al, 1991; Retsema et al., 1986). The greatest advantages of azithromycin compared to other macrolide antibiotics are its unusual pharmacokinetics: high tissue distribution and metabolic stability. These properties have led in recent years to the widespread use of the azalide scaffold for synthesis of new antibacterial active compounds with advantageous pharmacokinetics.
Fig. 1. Azithromycin (1) and its position subjected to derivatization

The growing resistance to antibiotics conferred by microorganisms commonly involved in respiratory tract infections has become a serious clinical problem (Prieto et al., 2002). The widespread use of macrolides has contributed to the increase of resistance within *Streptococcus pyogenes* and *Streptococcus pneumoniae* strains and its level varies worldwide, with an alarming upper rate of 25% in some European countries (Granizo et al., 2000; Szczyypa et al., 2000; Nagai et al., 2002; Albrich et al., 2004). Gram-positive *S. pyogenes* and *S. pneumonia* is the most common bacterial strains implicated in acute pharyngitis, skin and soft tissue infections and also one of the most problematic respiratory pathogen (Cunningham et al., 2000).

It has been shown that the resistance to macrolide antibiotics in Gram-positive microorganisms can be attributed to two main mechanisms: target site modification and active efflux (Nakajima et al., 1999). It is known that macrolides exert their activity by binding to the large 50S ribosomal subunit. They inhibit bacteria protein synthesis at peptidyl transferase center by blocking the nascent peptide exit tunnel (Poehlsgarrd & Douthwaite, 2003). The modification of specific rRNA bases can prevent macrolides to bind. This may be due to the action of methylases encoded either by *erm*(B) or *erm*(A) genes (Weisblum, 1998). The methylases are responsible for developing macrolide, lincosamide and streptogramin B (MLS$_{B}$) resistance; inducible-(iMLS) or constitutive (cMLS). The active drug efflux is another common type of resistance developed by bacteria and is mediated by the membrane-associated pump encoded by the *mef*(A) gene (Sutcliffe et al. 1996). In order to overcome the resistance problems, lots of efforts have been made worldwide to search for novel and more potent agents with all of the desirable features of the earlier generation of macrolides.

The discovery of highly potent representatives of the third-generation of macrolides, like ketolides (Agouridas 1998), acylides (Tanikawa et al. 2001; Tanikawa et al. 2003), anhydrolides (Elliott et al. 1998), etc., was a step forward to tackle the efflux problems (LeMahieu et al. 1974; Pestka & LeMahieu 1974a & 1974b, Pestka et al. 1974; Pestka et al. 1976; Allen. 1977; Van Bambeke et al. 2008)' to (Tanikawa et al., 2001; Tanikawa et al., 2003), anhydrolides (Elliott et al., 1998), etc., was a step forward to tackle the efflux problems (LeMahieu et al., 1974; Pestka & LeMahieu 1974a & 1974b, Pestka et al., 1974; Pestka et al., 1976; Allen. 1977; Van Bambeke et al., 2008).
However, some serious drawbacks have been observed for those compound classes: the emergence of resistance developed shortly after their introduction and rare but serious side effects which lead to restrictions and withdrawal (Bambeke et al., 2008) as seen recently with telithromycin, approved by the United States (USA) Food and Drug Administration (FDA) approved in 2004 by for treatment of mild to moderate community-acquired bacterial pneumonia (CABP) (Cruzan, 2007; Farrell et al., 2010).

Recently, considering azithromycin’s beneficial pharmacokinetic properties, our group have led the widespread modification of the azalide scaffold (Fig. 1) in a search for new, to resistant bacterial strains active azalides (Fajdetić et al., 2010; Fajdetić et al., 2011; Hutinec et al., 2010; Kapić et. al, 2010; Kapić et. al, 2011a; Kapić et. al., 2011b; Marušić Ištuk et al., 2011; Matanović Škugor et al., 2010; Palej Jakopović et al., 2010; Pavlović et al., 2010; Pavlović & Mutak, 2011; Štimac et al., 2010).

In this paper, we present the short overview leading to the discovery of novel sulfonylureas, ureas and thioureas of 15-membered azalides as a new class of compounds and their antibacterial activity against some key erythromycin resistant pathogens. Structural features that guided design of novel macrolides included (1) a properly attached aryl/heteroaryl-carbamoyl group for improving activity against MLSB resistance and (2) cleavage of cladinose sugar and ketolide backbone for improving potency and activity against efflux resistance. It was expected that introduction of unsaturated unit, that is, carbamoyl group, on nitrogen at position 9a of 1 (Fig. 1) will significantly change electronic properties and also steric environment in the ‘upper part’ of the macrolide. It will also serve as an excellent linker for the attachment of various groups allowing preparation of a library of compounds with the goal of identifying novel bacterial inhibitors.

2. Novel sulfonylureas, ureas and thioureas of 15-membered azalides

The first discovered representative of the 15-membered azalides, cyclic amine 2 (Scheme 1) named 9-deoxo-9a-aza-9a-homoerythromycin A, permitted a derivatisation line at the 9a-nitrogen atom (Scheme 1). Its first derivatization was methylation at 9a position and synthesis of 9-deoxo-9a-aza-9a-methyl-9a-homoerythromycin A, azithromycin (1)(Kobrehel & Djokić, 1982).

Several N-derivatisation lines of azalides skeleton were started in PLIVA in the early 1990s (Schönfeld & Mutak 2002; Mutak 2007), and some of the synthesized compounds showed antibacterial activity. In that respect, the observed activity of initially prepared 9a-N-carbamoyl and N-thiocarbamoyl derivatives of 2 (Kujundžić et al., 1995) encouraged us to extend our study in this direction.

Thus, a series of new sulfonylurea, urea and thiourea derivatives of 15-membered azalides were prepared in order to study whether antibacterial activity toward resistant strains would be achieved by introduction of aryl-sulfonylcarbamoyl/carbamoyl/thiocarbamoyl group into the azalide molecule and how the activity would be affected by nature and position of the substituents in the phenyl ring (Bukvić Krajačić et al., 2005). Of particular interest was to study the influence of the linker between sulfonylcarbamoyl/carbamoyl/thiocarbamoyl- group and
aglycon moiety on the antibacterial activity. A special attention was paid to achieving the activity against *S. pyogenes* and *S. pneumonia* resistant strains.

Scheme 1. Synthesis of sulfonylureas 3, 5 and 7.

### 2.1 Sulfonylureas

Intermediates 2 (Djokić et al., 1986; Djokić et al., 1988) and 4, smoothly reacted with substituted benzensulfonyl isocyanates to form 9a-N-[N’-(aryl)sulfonylcarbamoyl] derivatives, 3a-3f and 5a-5f in high yields (Scheme 1). The key intermediate, 9a-N-(γ-aminopropyl) derivative 4 was prepared by standard Michael addition of acrylonitrile to the amine 2, followed by catalytic hydrogenation of obtained 9a-N-(β-cyanoethyl) derivative with PtO₂ as a catalyst (Bright et al., 1988). Derivatives 7a-7f, were prepared by the selective cyanoethylation of amine 4 with equivalent amounts of acrylonitrile, followed by the addition of the substituted benzensulfonyl isocyanates to the intermediate 6.

For the sulfonylureas directly linked to macrocyclic ring 3a-3f it was observed that compounds with methyl group and chlorine in *p*- 3b (MIC 1 µg/ml), 3d (MIC 1 µg/ml) and *o-* 3c (MIC 0.5 µg/ml), 3e (MIC 2 µg/ml) positions and fluorine in *p*-position 3f (MIC 2 µg/ml) showed significantly improved activity against iMLS resistant *S. pyogenes* strain when compared to azithromycin 1 (MIC 8 µg/ml) and starting amine 2 (MIC 16 µg/ml). Also, these compounds exhibited two level of dilution better activity than 2 (MIC 0.25 µg/ml) and similar activity to 1 (MIC ≤0.125 µg/ml) against sensitive *S. pneumonia* (Bukvić Krajačić et al. 2005). However, the activities against Gram-negative bacteria were all lower than those for 1 and 2. Generally, it was observed that antibacterial activity of the novel
arylsulfonylcarbamoyl derivatives 3a-3f, 5a-5f and 7a-7f against all the tested erythromycin susceptible (Ery-S) Gram-positive strains decreased in the series 3a-3f > 5a-5f > 7a-7f by the introduction of a propyl linker and additional cyanoethyl side chain.

2.2 Novel ureas and thioureas & macrolide-sulfonamide conjugate

Various 9a-carbamoyl and thiocarbamoyl derivatives 8 & 9 were prepared (Scheme 2) by reaction of intermediate 2 with corresponding isocyanates or isothiocyanates (Kujundžić et al., 1995). Reactions were usually conducted in toluene to achieve easily crystallisable N-alkyl or N-aryl substituted ureas. Structures of the N-isopropyl– (8a) (Kujundžić et al., 1995) and N-(4-pyridyl)– (8g) (Sheldrick et al., 1995) derivatives were confirmed by single crystal X-ray analysis. In biological testing, only a few derivatives 8 & 9 showed moderate antibacterial activity. Additional halogen-aryl derivatives of 8 & 9 have been synthesized showing moderate activity against resistant strains (Marušić-Ištuk et al., 2000).

Introduction of novel interactive groups into the azalide backbone resulted in further improvements in activity. Strategy which involved macrolide conjugates incorporating antibacterial sulfonamides, such as sulfanilamide, sulfabenz, sulfapyridine and sulfamethoxazole, showed an increased affinity for the ribosome (Bukvić Krajačić et al., 2007). Significant activity against inducible resistant S. pyogenes strains was observed by modifications at position 9a of an azalide lacton ring, by the carbamoyl group linked sulfonamides (Scheme 3). Conjugates of 15-membered azalides and sulfonamides 10a-10d were prepared by the reaction of 2 (Djokić et al. 1986; Djokić et al. 1988) with 4-(chlorosulfonyl)phenylisocyanate. The smoothly formed 9a-(4-chlorosulfonylphenyl)-carbamoyl derivative was transformed without the isolation into the compounds 10a-10d, by the reaction of ammonia, aniline, 2-aminopyridine and 5-methyl-3-aminoisoxazole, respectively.

Azalide-sulfonamide conjugates 10a and 10b possess two to three times better activity against iMLS resistant S. pyogenes strain (MIC 2 µg/ml) when compared to both azithromycin 1 (MIC 8 µg/ml) and starting cyclic amine 2 (MIC 16 µg/ml) (Bukvić Krajačić et al., 2007). These activities are comparable to those observed for azalide sulfonylureas 3a-3f (Bukvić Krajačić et al., 2005). New azithromycin-sulfonamide conjugates 10a and 10b exhibit somewhat lower activity than 1 against sensitive S. pneumoniae and S. pyogenes strains. Furthermore, the 10c and 10d showed in general lower activity against most of the tested bacterial strains except for sensitive S. aureus and M. catarrhalis where better activity was observed in comparison with 10a and 10b analogs (Bukvić Krajačić et al., 2007).

Further expanding the range of antimicrobial activity, especially against MLSB and efflux-mediated resistant S. pyogenes and S. pneumoniae strains was achieved by introduction of carbamoyl and thiocarbamoyl groups attached on propyl linker at the 9a position (Bukvić Krajačić et al., 2009). Novel N’'-aryl substituted 9a-(N’-carbamoyl/thiocarbamoyl-γ-aminopropyl)- 11, 12 and 9a-[N’-β-cyanoethyl]-N’-(carbamoyl/thiocarbamoyl-γ-aminopropyl]- 13, 14 derivatives were obtained according to efficient procedure described for the preparation of the previous classes of compounds (Scheme 2) (Bukvić Krajačić et al., 2005 & 2007).
Ureas 11 and 13 and thioureas 12 and 14 (Bukvić Krajačić et al., 2009) showed a significant improvement in antibacterial activity against all tested macrolide-susceptible and resistant bacteria in comparison with carbamoyl/thiocarbamoyl derivatives 8 & 9 (Kujundžić et al. 1995), sulfonylcarbamoyl derivatives 3a-3f (Bukvić Krajačić et al., 2005) and azithromycin-sulfonamide conjugates 10a-10d (Bukvić Krajačić et al., 2007). Also, these compounds exhibited a substantially improved in vitro antimalarial activity against P. falciparum (Bukvić Krajačić et al., 2011b; Hutinec et al., 2011). Several ureas bearing naphthyl substituents (11f, 11g, 11h) were superior in vitro to the azithromycin against inducible resistant S. pyogenes (MIC 2 μg/ml). Ureas 11f, 11g and thiourea 12f also showed in vitro activity against efflux-mediated resistant S. pneumoniae (MIC 4 μg/ml), comparable to azithromycin (MIC 4 μg/ml).

In general, all tested compounds had high in vitro activity against erythromycin susceptible Gram-positive aerobes, S. pneumoniae and S. pyogenes (MIC ≤ 0.125 μg/ml) (Bukvić Krajačić et al., 2009). Ureas 11 and 13 and thioureas 12 and 14 exhibited excellent activity against susceptible S. aureus (MIC 0.25-1 μg/ml), but lacked activity against resistant S. aureus strains. Ureas 11f, 11g and thiourea 12f also showed in vitro activity against efflux-mediated resistant S. pneumoniae with MICs 4 μg/ml and their activities were comparable with those observed for azithromycin (MIC 8 μg/ml). Ureas 11g, 11h and 13h showed moderate activity against cMLS S. pneumonia (MIC 16 μg/ml) (Bukvić Krajačić et al., 2009). In vitro activities of ureas 11 and 13, thioureas 12 and 14 against key community-acquired Gram-negative respiratory pathogens
were improved in comparison with sulfonylureas 3a-3f (Bukvić Krajačić et al., 2005) and azithromycin-sulfonamide conjugates 10a-10d (Bukvić Krajačić et al., 2007). Ureas 11f, 11g and 11h demonstrated high activity against Moraxella catarrhalis. Naphthyl substituted ureas 11f, 11g and 11h showed better activity against Gram-negative pathogens involved in respiratory tract infections (RTI), M. catarrhalis (MIC 0.25 µg/ml) and H. influenza (MIC 1 µg/ml) than derivatives with phenyl ring on the alkyl side-chain 11b-11d. In case of phenylethyl-substituents in 11d and 12d the presence of thiocarbamoyl moiety seemed to improve activity against H. influenzae. The urea 13 with cyanoethyl chain showed similar antibacterial activity in comparison to the urea 11. The observed antibacterial activity of ureas and thiureas increased in the series 8 & 9 < 11 & 12 < 13 & 14, by the introduction of a propyl linker and additional cyanoethyl side-chain (Bukvić Krajačić et al., 2009).

On the basis of excellent in vitro antibacterial activity and their structural similarity, several compounds 11f, 11g, 11h, 12c, 12d, 12e, 12f, 13h, 14c, 14d, 14e were screened for acid stability, cytotoxicity and preliminary pharmacokinetic parameters. In acidic conditions compounds exhibited azithromycin like stability (Bukvić Krajačić et al., 2009). In vitro cytotoxicity on Hep G2 and THP-1 cell lines measured for the selected set of compounds revealed that all compounds showed relatively low cytotoxicity in vitro (IC50s ≥ 4 µM) (Bukvić Krajačić et al., 2011b). These marked them as potent and selective compounds for further profiling (Steinmeyer, 2006). Metabolic stability of ureas and thioureas were screened in vitro using human and mouse liver microsomes and only a few were selected for in vivo rat pharmacokinetic studies in order to determine their pharmacokinetic profiles (Table 1) (Bukvić Krajačić et al., 2011b). All compounds demonstrated good in vitro, metabolic stability with t1/2 greater than 120 min (t1/2 = 103 min for compound 14d in human liver microsomes). As was observed with azithromycin, and in line with the in vitro data, these analogs had a low systemic clearance, moderate to high volume of distribution and a very long half-life, however, the oral bioavailability was low (12c, 12e) to moderate (Bukvić Krajačić et al., 2011b).

CL - blood clearance, Vd - apparent volume of distribution at the terminal phase based on drug concentration in blood, t1/2 - half life, a - IV parameters determined in one rat

Table 1. Pharmacokinetic parameters estimated in blood after intravenous (IV) and oral gavage (PO) administration to Sprague-Dawley rats (10 mg/kg IV and 30 mg/kg PO) (Bukvić Krajačić t al., 2011b).

Preliminary in vitro microsomal stability data indicated that these compounds had good metabolic stability, as was confirmed by low clearances in vivo for the compounds tested. In comparison to azithromycin, known for its extensive tissue distribution, (Schönfeld & Mutak, 2002) these derivatives had a tendency toward higher volumes of distribution, in line with their increased lipophilic character (approx. 2-3 log units higher than azithromycin, according to calculated logP values, data not shown) due to the presence of strong lipophilic aromatic phenyl and naphtyl rings in the 9a-N substituent (Bukvić Krajačić et al., 2011b). Overall, with increased in vitro activity and promising pharmacokinetic properties, this series of molecules represents a good starting platform for the design of novel antibacterial and antimalarial azalides.
2.3 3-Decladinosyl-derivatives of sulfonylureas, ureas and thioureas

Introduction of unsaturated, sp² hybridized, carbamoyl unit at 9a position placed nitrogen atom of 2 significantly change electronic properties and also steric environment in the ‘upper part’ of the macrolide, what resulted in increased antibacterial activity of the novel sulfonylureas 3,5,7 (Bukvić Krajačić et al., 2005), azalide-sulfonamide conjugates 10 (Bukvić Krajačić et al., 2007), and ureas and thioureas 11-14 (Bukvić Krajačić et al., 2009). On the other hand, the selectively achieved cleavage of cladinose sugar, significantly changes the structural behaviour of the ‘lower part’ of 9a-carbamoyl 15-membered azalides, leading to the 3-O-decladinosyl-3-hydroxy ureas and thiouras lacking of any, as expected, antibacterial activity (Bukvić Krajačić et al., 2005; Bukvić Krajačić et al., 2007; Marušić Ištuk et al., 2007).

However, there are some novel highly potent 3-O-decladinosyl derivatives of 14-membered macrolides, e.g. ketolides (Agouridas et al, 1998), acylides (Tanikawa et al., 2001; Tanikawa et al., 2003), anhydrolides (Elliott et al., 1998), etc. (Schönfeld & Kirst 2002; Pal 2006; Kaneko et al., 2006; Mutak 2007) (Fig. 2), proved active against resistant bacterial strains.

Fig. 2. Novel classes of 3-O-decladinosyl derivatives of 14- and 15-membered macrolides
2.3.1 3-Decladinosyl-3-O-substituted derivatives

Isopropyl- and 2,4-dichlorophenyl- derivatives of 9a-carbamoyl-6-hydroxy (17 & 18) and 9a-carbamoyl-6-methoxy azalides (19 & 20) lacking any antibacterial activity, were selected to study the effects of the ‘lower part’ of azalide skeleton modifications via chemical transformations of hydroxyl group at C-3 position (Scheme 3) (Marušić Ištuk et al., 2007). They afforded formation of the new ketolides 23 and 24, anhydrolides 27 and 28, hemiketals 21 and 22, cyclic ethers 25 and 26, and acylides 29 and 30 (Scheme 4). In order to perform chemical transformations on the hydroxyl group at position 3, 2'-hydroxyl group which is the most reactive one, was suitably protected. Consequently, reaction of 3-decladinosyl-3-hydroxy- azalides 17, 18, 19, and 20 with acetic anhydride in the presence of a base smoothly afforded 2'-O-acetyl-3-decladinosyl-3-hydroxy-6-hydroxy azalides, that under conditions of Pfitzner–Moffat 3-OH group oxidation, followed by subsequent methanolysis of 2'-O-acetyl intermediate produces internal 3,6-hemiketal structures 21 and 22. Under the same reaction conditions 2'-O-acetyl-3-decladinosyl-3-hydroxy-6-methoxy derivatives afford 3-keto azalides 23 and 24 (Scheme 3). Introduction of mesyl group at position C-3 of 6-hydroxy-, 17

Scheme 3. Synthesis of 3-decladinosyl-3-O-substituted azalides
& 18, and 6-methoxy-, 19 & 20 derivatives and subsequent base-promoted elimination led to the formation of different products. Whereas 6-hydroxy derivatives 17 & 18 produce 3,6-cyclic ethers 25 and 26, 6-methoxy derivatives 19 & 20 afford 2,3-anhydro azalides 27 and 28.

Among already known 3-acyclides of 14-membered macrolides, 3-O-(4-nitrophenyl)acetyl derivative of clarithromycin (TEA-0777) showed the best antibacterial activity (Tanikawa et al., 2001). Accordingly, 9a-carbamoyl acylides having (4-nitrophenyl)acetyl- functionality attached to 3-O position, azalides 29 and 30, were prepared, to test if antibacterial activity could be enhanced upon attachment of favorite side-arm.

3-Decladinosyl-6-hydroxy and 6-methoxy azalides 15 and 16 and 9a-carbamoyl/9a-thiocarbamoyl derivatives 17, 18, 19 & 20 proved antibacterially inactive against tested strains. Similar situation can be seen with 3,6-hemiketals 21 & 22 and 3,6-cyclic ethers 25 & 26. However, anhydrolides 27 and 28 as well as ketolides 23 and 24 show good antibacterial activity against efflux resistant S. pneumonia but lower in comparison to erythromycin. 9a-Carbamolyl-3-O-(4-nitrophenyl)acetyl- acylides 29 and 30 showed the best antibacterial activity against efflux resistant S. pneumoniae (MIC 4 µg/ml), and better in comparison to erythromycin (MIC 8 µg/ml). Acylides 29 and 30 also show weak activity against erythromycin-resistant S. aureus (Marušić Ištuk et al., 2007).

2.3.2 3-Decladinosyl-3-hydroxy derivatives

As expected, 3-decladinosyl-3-hydroxy- azalides 17 – 20 and 31 - 34 (Fig. 3) lacked any significant antimicrobial activity (Marušić Ištuk et al., 2007; Bukvić Kraljić et al., 2005; Bukvić Krajačić et al., 2007) being consistent with the role cladinoase was found to play in antimicrobial activity (LeMahieu et al., 1974; Kaneko et al., 2006; Pal, 2006; Tanikawa et al., 2001; Mutak, 2007).

![Fig. 3. 3-Decladinosyl-3-hydroxy- azalides from the urea, thiorea and sulfonlylurea series, lacking any significant antimicrobial activity](attachment:image.png)
This is supported by recently published NMR binding studies (trNOESY and STD experiments) on 6-O-methyl-homoerythromycin derivatives, showing that the absence of cladinose sugar has been found to be the main cause of their inability to bind to their target ribosome (Novak et al., 2009). Stability study of the most active compounds 11f and 13f in the artificial gastric juice (Bukvić Krajačić et al., 2009) led to the formation of two decladinosyl derivatives 33a and 34a which were tested only against panel of S. pneumoniae strains. As was expected decladinosyl urea derivative 34a did not show activity against tested strains. However, decladinosyl urea derivative 33a showed significant activity against erythromycin susceptible S. pneumoniae strain (1 µg/ml), as well as efflux-mediated S. pneumoniae resistant strain (8 µg/ml) comparable to azithromycin. This finding initiated the synthesis of a small library of 3-decladinosyl-3-hydroxy ureas and thioureas of 15-membered azalides termed “decladinosylides” (Bukvić Krajačić et al., 2011a).

High reactivity of secondary and primary amino groups of 3-decladinosyl- derivatives 37 and 38 toward isocyanates and isothiocyanates assured highly site-selective introduction of carbamoyl and thiocarbamoyl groups and preparation of ureas 33 & 34 and thioureas 35 & 36 in high yield (Scheme 4). They were found to posses good antibacterial activities against key respiratory Gram-positive and Gram-negative pathogens including efflux-mediated resistant strains.

Among them, most of the synthesized 3-decladinosyl-3-hydroxy derivatives showed moderate to high activity against efflux-mediated resistant S. pneumoniae and moderate activity against susceptible S. pneumoniae and S. pyogenes strains. Against efflux-mediated resistant S. pneumoniae compound 35a (MIC 2 µg/ml) posses better activity compared to azithromycin (1) (MIC 8 µg/ml) (Bukvić Krajačić et al., 2011a) and their parent 3-cladinosyl analogues 11 & 13 (MIC 4 to 16 µg/ml) (Bukvić Krajačić et al., 2009), and significantly better in comparison to the 3-decladinosyl-3-hydroxy azithromycin (16) (MIC >64 µg/ml).

The racemic urea derivative 33c showed the highest activity against both, susceptible S. pneumoniae and S. pyogenes strains, and the same activity as its 3-cladinosyl analogue (±)-11h and azithromycin (MIC ≤0.125 µg/ml) (Bukvić Krajačić et al., 2009).

Interestingly, some of discovered 3-decladinosyl-3-hydroxy ureas 33 & 34, and thioureas 35 & 36, maintain antibacterial activity against Gram-negative pathogens H. influenzae and M. catarrhalis (Bukvić Krajačić et al., 2011a) in comparison to their parent 3-cladinosyl derivatives 11, 12, 13 & 14, (Bukvić Krajačić et al., 2009) and demonstrate large improvement in comparison to the inactive 3-decladinosyl sulfonylureas 31 (Bukvić Krajačić et al., 2005).
and 3-decladinosyl azithromycin-sulfonamide conjugates 32 (Bukvić Krajačić et al., 2007). Activity of (±)-33a and 35a against *H. influenzae* is only one dilution lower than the corresponding MIC of azithromycin (MIC 2 µg/ml). Urea (±)-33c was more potent (MIC 8 µg/ml) than its 3-cladinosyl analogue (±)-11h (MIC 16 µg/ml) against *Enterococcus faecalis* and 33a showed the same activity against *E. coli* in comparison to its cladinosyl analogue 11f. (Bukvić Krajačić et al., 2011a).

Thus, it seems that appropriate linked urea or thiourea moiety at 9a-N of 3-decladinosyl-3-hydroxy- azalides might interact with particular ribosome binding sites and “substitute” the cladinose sugar interaction. In order to gain more information about that conformational analysis of a compound 35a was carried out by using systematic conformational search around flexible propyl linker. Analysis of NOE cross peaks in the NOESY spectrum indicated that there is no strong interaction between macrolactone ring and the substituent at 9a-position of 35a, pointing to the stretched conformations that were also found to be most stable ones in the conformational analysis (Bukvić Krajačić et al., 2011a). Superposed x-ray conformations of ABT-773, (Auerbach et al., 2009), azithromycin (Schlunzen et al., 2003; Hansen et al., 2002), two bound conformations of telithromycin from *Deinococcus radiodurans* (Berisio et al. 2003) and *Haloarcula marismortui* (Hansen et al., 2002) and the lowest conformation for compound 35a were shown in Fig. 4 (Bukvić Krajačić et al., 2011a).

![Fig. 4. Superposed x-ray conformations for azithromycin (green) (Hansen et al., 2002), ABT-773 (cyan) (Auerbach et al., 2009), two conformations of telithromycin from *Deinococcus radiodurans* (magenta) (Berisio et al. 2003) and *Haloarcula marismortui* (yellow) (Hansen et al., 2002) complexes and most stable conformation for compound 35a (red) (Bukvić Krajačić et al., 2011a).](image-url)

It is clear that substituents at different positions have different spatial arrangements with respect to macrolactone. Until now there is a number of evidence including here mentioned ketolides (Auerbach et al., 2009; Schlunzen et al., 2003; Hansen et al., 2002; Berisio et al., 2003), that high structural diversity is tolerated within the flexible macrolide-binding site of
ribosome. In spite of the knowledge gained so far on macrolide binding, (Novak et al., 2006; Novak et al., 2009; Auerbach et al., 2009; Schlunzen et al., 2003; Hansen et al., 2002; Berisio et al., 2003) an understanding of the mode of their interactions with ribosome still remain incomplete with many issues unresolved. Therefore, it can only be speculated about the possible binding mode of the compound 35a but it is likely that the additional interaction involving 1-naphthyl-propyl- side-chain, attached at the 9a position, might lead to a further stabilization of a complex with ribosome (Bukvić Krajačić et al., 2011a).

3. Concluding remarks

In summary, the coupling of a arylsulfonyl and benzenesulfonamido moiety to the 9a position of 15-membered azalide scaffold via carbamoyl linker has indicated improvement in antibacterial activity of novel azalides.

Fig. 5. Antibacterial activities of urea and thiourea derivatives of 15-membered azalides in comparison to sulfonylurea analogues.
Hence, newly synthesised sulfonyl ureas of azalides 3b-3f, and azalide-sulfonamide conjugates 10a and 10b displayed significantly improved activity against inducible resistant *S. pyogenes* strain when compared to azithromycin.

In addition, the introduction of carbamoyl and thiocarbamoyl group at the 9a position of azithromycin like azalide skeleton via propyl linker proved to be promising method to tackle the resistance problems.

As a result of a preliminary optimization of an alkyl/aryl moiety attached at the carbamoyl and thiocarbamoyl group all prepared and tested compounds had high *in vitro* activity against erythromycin susceptible Gram-positive aerobes and Gram-negative microorganisms and especially resistant *S. pyogenes* and *S. pneumoniae* strains. It was also, shown here that urea and thiourea derivatives of 3-decladinosyl-3-hydroxy azalides, although lacking a cladinose sugar, showed noticeable antibacterial activity.

Overall mutual comparison of obtained results can be summarized in three items:

- The observed increase of antibacterial activity in the series of ureas and thioureas 11, 12, 13 and 14 (Bukvić Krajačić et al., 2009) in comparison with those of their analogues 8 and 9 (Kujundžić et al., 1995), was opposite to the results obtained for the sulfonylcarbamoyl derivatives 3, 5 and 7 (Bukvić Krajačić et al., 2005) where a decrease of activity was found when sulfonylcarbamoyl moiety was further away from the azalide ring (Fig. 6)

![Fig. 6. Antibacterial activity of selected novel sulfonylureas, ureas and thioureas of 15-membered azalides on *S. Pneumoniae* efflux-mediated (Bukvić Krajačić et al., 2009) and *S. pyogenes* iMLS (Bukvić Krajačić et al., 2005) resistant strains in comparison to azithromycin](image)

- Several novel sulfonylureas (Bukvić Krajačić et al., 2005), ureas and thioureas (Bukvić Krajačić et al. 2009) of 15-membered azalides showed same or significantly better activity
on *S. pneumoniae* efflux-mediated and *S. pyogenes* iMLS resistant strains in comparison to azithromycin (Fig 7). Among them, new ureas with naphthyl substituents (11f, 11g & 11h) showed better activity against inducible resistant *S. pyogenes* in comparison to azithromycin. Ureas 11f & 11g and thioureas 12c, 12d, 12e and 12f possess good activity against efflux-mediated resistant *S. pyogenes*, comparable to azithromycin.

Fig. 7. Antibacterial activity of 3-decladinosyl-3-hydroxy ureas and thioureas on *S. pneumoniae* efflux-mediated resistant strain (Bukvić Krajačić et al., 2011) in comparison to their parent 3-cladinosyl analogues (Bukvić Krajačić et al., 2009) and test standards azithromycin (1) and 3-decladinosyl azithromycin (16).

- Contrary to the well known fact (LeMahieu, et.al., 1974; Kaneko et.al., 2006; Pal, 2006; Tanikawa, et.al., 2001; Mutak, 2007) and previous results (Bukvić Krajačić et al., 2005, Bukvić Krajačić et al., 2007; Marušić Ištuk et al., 2007), that simple removal of cladinose sugar from macrolides significantly decreases antibacterial activity, unexpectedly, some of the newly discovered 3-decladinosyl-3-hydroxy ureas 33 & 34, and thioureas 35 & 36 (Bukvić Krajačić et al., 2011) maintain good antibacterial activity against panel of key respiratory Gram-positive and Gram-negative pathogens. Against efflux-mediated resistant *S. pneumoniae* strain they posses comparable or better activity (MIC 2 -16 µg/ml) to their 3-cladinosyl parent analogues 11 & 13 (MIC 4 -16 µg/ml) (Bukvić Krajačić et al., 2009) and azithromycin (1) (MIC 8 µg/ml), and significantly better in comparison to the inactive 3-decladinosyl azithromycin (16) (MIC >64 µg/ml) (Fig. 7) (Bukvić Krajačić et al., 2011). Also, some 3-decladinosyl-3-hydroxy ureas 33 & 34, and thioureas 35 & 36, maintain antibacterial activity against Gram-negative pathogens *H. influenzae* and *M. catarrhalis* in comparison to their parent 3-cladinosyl derivatives (Bukvić Krajačić et al., 2009), and comparable to azithromycin, but demonstrate a large improvement in comparison with inactive 3-decladinosyl azithromycin 16 (Bukvić Krajačić et al., 2011) and other 3-decladinosyl derivatives reported in literature. These small library of 3-decladinosyl-3-hydroxy ureas and thioureas of 15-membered azalides we termed “decladinosylides.”
In general, novel sulfonylureas, ureas and thioureas of 15-membered azalides and their 3-decladinosyl-3-hydroxy derivatives showed their potential to serve as a good platform for further investigation in order to discover new derivatives having an improved overall biological profile with a special emphasis on resistant bacterial strains.
