1. Introduction

One of the main objectives of current research on walking robots is to make their gaits more fluid by introducing imbalance phases. For example, for walking robots without actuated ankles, which are under actuated in single support, dynamically stable walking gaits have been designed with success (Aoustin & Formal’sky 2003; Chevallereau et al. 2003; Zonfrilli et al. 2002; Aoustin et al. 2006; Pratt et al. 2001; Westervelt et al. 2003). Both the design of reference motions and trajectories and the control of the mechanism along these trajectories usually require the knowledge of the whole state of the robot. This state contains internal variables which are easy to measure using encoders for example, and also the absolute orientation of the walking robot with respect to the horizontal plane. For robots with unilateral constraints with the ground, it may not be possible to derive the latter information from internal measurements, as in the case of the absolute orientation of a biped in single support. Of course, technological solutions exist such as accelerometers, gyrometers, inertial units… But the implementation of these solutions is expensive and difficult.

In order to overcome these difficulties, we propose to use a state observer which, based on the measurements of the joint variables and on a dynamic model of the robot, provides estimates of the absolute orientation of the walking robot during imbalance phases. This strategy was first validated in simulation for a three link biped without feet, using nonlinear high gain observers and a nonlinear observer based on sliding modes with a finite time convergence (Lebastard et al. 2006a) and (Lebastard et al. 2006b), for walking gaits composed of single support phases and impacts. The main drawback with this family of observers is that, when only some of the degrees of freedom are measured, a state coordinates transformation is necessary to design their canonical form (Gauthier & Bornard 1981; Krener & Respondek 1985; Bornard & Hammouri 1991; Plestan & Glumineau 1997).

In this chapter, the observer is an extended Kalman filter and it is applied to SemiQuad, a prototype walking robot built at our institute. SemiQuad is a five link mechanism with a platform and two double-link legs. It is designed to study quadruped gaits where both front legs (resp. rear legs) have identical movements. Its unique front leg (resp. rear leg) acts as the two front legs (resp. rear legs) of the quadruped, so that SemiQuad can be considered as an implementation of a virtual quadruped, hence its
The legs have passive (uncontrolled) feet that extend in the frontal plane. Due to this, the robot is stable in the frontal plane. Four motors located in haunches and knees drive the mechanism. The locomotion of the prototype is a planar curvilinear gait. In double support, our prototype is statically stable and overactuated. In single support, it is unstable and underactuated.

The reference walking gaits have been designed using an intuitive strategy which is such that the absolute orientation is not required. Still, it contains imbalance phases during which the observer can be used, and its results evaluated. The estimation results being correct, such an observer can be used for contexts where the absolute angle is necessary. Furthermore, the idea can be useful for other types of walking robots, such as bipeds with imbalance phases.

The organization of this chapter is the following. Section 2 is devoted to the model of SemiQuad. It also contains the data of its physical parameters. The intuitive gaits which were designed for SemiQuad are presented in section 3. The statement of the problem of estimation of the absolute orientation of SemiQuad is defined in Section 4. Simulation results and experimental results are presented in section 5. Section 6 presents our conclusions and perspectives.

2. Presentation and dynamic models of SemiQuad

2.1 SemiQuad

The prototype (see figure 1) is composed of a platform and two identical double-link legs with knees. The legs have passive (uncontrolled) feet that extend in the frontal plane. Thus, the robot can only execute 2D motions in the sagittal plane, as considered here. There are four electrical DC motors with gearbox reducers to actuate the haunch joints between the platform and the thighs and the knee joints. Using a dynamic simulation, we have chosen parameters of the prototype (the sizes, masses, inertia moments of the links) and convenient actuators. The parameters of the four actuators with their gearbox reducers are specified in Table 1. The lengths, masses and inertia moments of each link of SemiQuad are specified in Table 2.

Table 1. Parameters of actuators

| physical parameters |
|---|---|---|---|
| of each link | mass (kg) | length (m) | Center of mass locations (m) |
| links 1 and 5: shin | $m_1 = m_5 = 0.40$ | $l_1 = l_5 = 0.15$ | $s_1 = s_5 = 0.083$ |
| link 3: platform +actuators in each haunch | $m_3 = 6.618$ | $l_3 = 0.375$ | $s_3 = 0.1875$ |
| links 2 and 4: thigh +actuators in each knee | $m_2 = m_4 = 3.21$ | $l_2 = l_4 = 0.15$ | $s_2 = s_4 = 0.139$ |
| | | | $l_2 = l_4 = 0.0043$ |

Table 2. Parameters of SemiQuad

The maximum value of the torque in the output shaft of each motor gearbox is 40 N.m. This saturation on the torques is taken into account to design the control law in simulation and in experiments. The total mass of the quadruped is approximately 14 kg. The four actuated joints of the robot are each equipped with one encoder to measure the angular position. The angular velocities are calculated using the angular positions. Currently the absolute platform orientation angle $\alpha$ (see figure 2) is not measured. As explained before, the proposed walking gait does not require this measurement. Each encoder has 2000 pts/rev and is attached directly to the motor shaft. The bandwidth of each joint of the robot is determined by the transfer function of the mechanical power train (motors, gearboxes) and the motor amplifiers that drive each motor. In the case of SemiQuad, we have approximately a 16 Hz bandwidth in the mechanical part of the joints and approximately 1.7 kHz for the amplifiers. The control computations are performed with a sample period of 5 ms (200 Hz). The software is developed in C language.

Fig. 2. SemiQuad's diagram: generalized coordinates, torques, forces applied to the leg tips, locations of mass centers.
2.2 Dynamic model of SemiQuad

Figure 2 gives the notations of the torques, the ground reactions, the joint variables and the Cartesian position of the platform. Using the equations of Lagrange, the dynamic model of SemiQuad can be written:

\[ D_1 \dot{q} + H_1 \dot{q} + G = B_1 \Gamma + D_2 R_1 + D_3 R_2 \]  

(1)

with \( q = [q_1, q_2, \ldots, q_7]^T \). The vector \( q \) is composed of the joint actuated variables and the absolute orientation of the platform, \( q = [\theta_1, \theta_2, \theta_3, \alpha]^T; (x_p, z_p) \) are the Cartesian coordinates of the platform center. The joint angle variables are positive for counter clockwise motion. \( D_1(q) \) is the inertia positive definite matrix. The matrix \( H(q, \dot{q}) \) represents the Coriolis and centrifugal forces and \( G(q) \) is the vector of the gravity forces. \( B_1 \) is a constant matrix composed of ones and zeros. Each matrix \( D_j(q) \) is a jacobian matrix which represents the relation between feet Cartesian velocities and angular velocities. It allows to take into account the ground reaction \( R_i \) on each foot. If foot \( j \) is not in contact with the ground, then \( R_j = [0,0]^T \). The term \( \Gamma = [\Gamma_1, \Gamma_2, \Gamma_3, \Gamma_4]^T \) is the vector of four actuator torques. Let us assume that during the single support, the stance leg acts as a pivot joint. Our hypothesis is that the contact of the swing leg with the ground results in no rebound and no slipping of the swing leg. Then, in single support, equation (1) can be simplified and rewritten as:

\[ D_1 \dot{q} + H_1 \dot{q} + G = B_1 \Gamma \]  

(2)

As the kinetic energy \( K = \frac{1}{2} q^T D_1 q \) does not depend on the choice of the absolute frame (see (Spong, M. & Vidyasagar M. 1991)) and furthermore variable \( \alpha \) defines the absolute orientation of SemiQuad, the inertia matrix \( D_1(5 \times 5) \) does not depend on \( \alpha \), and then \( D = D(\theta_1, \theta_2, \theta_3, \alpha) \). As for the case of equation (1), the matrix \( H(q, \dot{q}) \) represents the Coriolis and centrifugal forces and \( G(q) \) is the vector of gravity forces. \( B_1 \) is a constant matrix composed of ones and zeros. Equation (2) can be written under the following state form:

\[ x = \begin{bmatrix} \dot{q} \\ D_1^{-1}(-H_1 \dot{q} - G + B_1 \Gamma) \end{bmatrix} = f(x) + g(q_{rel}) \Gamma \]  

(3)

With \( x = [ \dot{q}^T, \dot{\alpha}^T ]^T \) and the joint angle vector \( \dot{q}_{rel} = [\theta_1, \theta_2, \theta_3]^T \). The state space is defined as \( x \in \mathbb{R}^{10} = \{ x = [\dot{q}^T, \dot{\alpha}^T] | [\dot{\alpha}] < \dot{\alpha}_{max} < \infty; \dot{q} \in [-\pi, \pi]^T \} \}. From these definitions, it is clear that all state coordinates are bounded.

2.3 Discrete Model

Our objective is to design an extended Kalman filter with a sampling period \( \Delta \) to observe the absolute orientation \( \alpha \). Then it is necessary to find a discrete model equivalent to (3). A possible solution is to write \( \dot{x} = \frac{x_{k+1} - x_k}{\Delta} \) and (3) becomes:
For SemiQuad, we have preferred to sample the generalized coordinates and their velocities using approximations to a different order by a Taylor development:

\[
x(t + \Delta) = x(t) + \Delta \frac{\partial x(q)}{\partial q} + \frac{\Delta^2}{2!} \frac{\partial^2 x(q)}{\partial q^2} + \ldots + \frac{\Delta^n}{n!} \frac{\partial^n x(q)}{\partial q^n} + \varepsilon,
\]

(5)

From (5), developments to second order and first order have been used for the generalized coordinates and their velocities, respectively. Limiting the order where possible limits the noise, but using second order developments for position variables introduces their second order derivative and allows to make use of the dynamic model.

\[
\begin{pmatrix}
q_{k+1} \\
\dot{q}_{k+1}
\end{pmatrix} = \begin{pmatrix}
q_k \\
\dot{q}_k
\end{pmatrix} + \Delta \begin{pmatrix}
\frac{\partial x(q)}{\partial q} \\
\frac{\partial \dot{x}(q)}{\partial q}
\end{pmatrix}_{\frac{k}{k}} + \frac{\Delta^2}{2!} \begin{pmatrix}
\frac{\partial^2 x(q)}{\partial q^2} \\
\frac{\partial^2 \dot{x}(q)}{\partial q^2}
\end{pmatrix}_{\frac{k}{k}} + \begin{pmatrix} 0_M \end{pmatrix}_{k+1}
\]

(6)

With this method, a discrete model of (3) is calculated. If we add the equation corresponding to the measurement of the joint angles, we obtain the following system:

\[
\begin{align*}
x_{k+1} &= f(x_k, I_k) \\
y_k &= h(x_k) = (\theta_1, \theta_2, \theta_3)^T = Cx_k \quad \text{with} \quad C = I_{sxt}
\end{align*}
\]

(7)

2.4 Impulsive impact equation

The impact occurs at the end of the imbalance phase, when the swing leg tip touches the ground, i.e.:

\[x \in S = \{x \in X \mid q = q_i\}\]

where \(q_i\) is the final configuration of SemiQuad. The instant of impact is denoted by \(T_i\). Let us use the index 2 for the swing leg, and 1 for the stance leg during the imbalance phase in single support. We assume that:

\[\begin{align*}
&\text{the impact is passive, absolutely inelastic;} \\
&\text{the swing leg does not slip when it touches the ground;} \\
&\text{the previous stance leg does not take off;} \\
&\text{the configuration of the robot does not change at the instant of impact.}
\end{align*}\]

Given these conditions, at the instant of an impact, the contact can be considered as impulsive forces and defined by Dirac delta-functions \(R_j = I_{k} \Delta(t - T_i)\) (\(j=1, 2\)). Here \(I_{k} = [I_{k_1} 0_M]_k\), is the vector of the magnitudes of the impulsive reaction in leg \(j\) (Formal’sky 1974). The impact model is calculated by integrating (1) between \(T_i\) (just before impact) and \(T_i^*\) (just after impact). The torques provided by the actuators at the joints, and Coriolis and gravity forces, have finite values, thus they do not influence the impact. Consequently the impact equation can be written in the following matrix form:

\[
D_k(q)(\dot{q}_i^* - \dot{q}_i) = D_{k_1}(q)I_{k_1} + D_{k_2}(q)I_{k_2}
\]

(8)

Here, \(q\) is the configuration of SemiQuad at \(t = T_i\), \(\dot{q}_i^*\) and \(\dot{q}_i\) are the angular velocities just before and just after impact, respectively. Furthermore, the velocity of the stance leg tip before impact is null. Then we have:
\[
D_k \ddot{q}_k^* = 0_{2x1} 
\] 
After impact, both legs are stance legs, and the velocity of their tip becomes null: 
\[
\begin{pmatrix} D_k^T \\ D_k \\ \end{pmatrix} \ddot{q}_k = 0_{4x1} 
\]

3. Walking gait strategy for SemiQuad

By analogy with animal gaits with no flight phase, SemiQuad must jump with front or back leg to realize a walking gait. There is no other way to avoid leg sliding. Then it is necessary to take into account that SemiQuad is under actuated in single support and over actuated in double support. Let us briefly present the adopted strategy to realize a walking gait for SemiQuad. It was tested first in simulation to study its feasibility and then experimentally (Aoustin et al. 2006). A video can be found on the web page http://www.irccyn.ec-nantes.fr/irccyn/d/en/equipes/Robotique/Themes/Mobile. Figure 4 represents a sequence of stick configurations for one step to illustrate the gait. Let us consider half step \( n \) as the current half step, which is composed of a double support, a single support on the rear leg and an impact on the ground. During the double support, SemiQuad has only three degrees of freedom. Then its movement can be completely prescribed with the four actuators. A reference movement is chosen to transfer the platform centre backwards. This is done by defining a polynomial of third order for both Cartesian coordinates \( x_p \) and \( z_p \). The coefficients of these polynomials are calculated from a choice of initial and final positions, of the initial velocity and an intermediate position of the platform centre. The reference trajectories for the four actuated joint variables are calculated with an inverse geometric model. Then, by folding and immediately thrusting the front leg, the single support phase on the rear leg starts. During this imbalance phase, SemiQuad has five degrees of freedom and its rotation is free around its stance leg tip in the sagittal plane. Reference trajectories are specified with third order polynomial functions in time for the four actuated inter-link angles. However, the final time \( t_p \) of these polynomial functions is chosen smaller than the calculated duration \( T_{ss} \) of the single support phase, such that before impact the four desired inter-link angles \( \theta_d(id) = 1,\ldots,4 \) become constant. Using this strategy, we obtain the desired final configuration of our prototype before the impact even if \( T_{ss} \) is not equal to the expected value.

\[
\theta_d = a_0 + a_1t + a_2t^2 + a_3t^3 \quad \text{if} \quad t < t_p \\
\theta_d = \theta_m(T_p) \quad \text{if} \quad t_p \leq t \leq T_m 
\]

The coefficients of these polynomials are calculated from a choice of initial, intermediate and final configurations and of the initial velocity for each joint link. Just after impact, the next half step begins and a similar strategy is applied (figure 4). The tracking of the reference trajectories is achieved using a PD controller. The gains, which were adjusted using pole placement, were tested in simulation and in experiments. Figure 3 shows the evolutions of the absolute orientation variable \( \alpha(t) \) and its velocity \( \dot{\alpha}(t) \), obtained from the simulation of SemiQuad for five steps. These graphs clearly show that the dynamics of the absolute orientation cannot be neglected in the design of a control law based on a state feedback. The
durations of the double support phase and the single support phase are 1.5 s and 0.4 s respectively.

Fig. 3. Evolution of $\alpha(t)$ and $\dot{\alpha}(t)$ in simulation during the walking gait for five steps.

### 4. Observation of the absolute orientation of SemiQuad

System (3) is generically observable if the following matrix $O$ has a full rank (see (Plestan & Glumineau 1997)), which is equal to 10, with $(k_1,\ldots,k_p)$ the observability indexes.

$$O = \left( \frac{d}{h_1}, \ldots, \frac{d^2}{h_1}, \ldots, \frac{d}{h_p}, \ldots, \frac{d^p}{h_p} \right)$$

where $\frac{d}{h}$ is the gradient vector of function $h$ (see system (7)) with respect to the state vector $x$, and $\frac{d^p}{h}$ is the Lie derivative of $h$ along the vector field $f$. We have also checked that the equivalent property is satisfied by the discrete model. This means that, at each sampling time $t_k$, it is possible to find an observability matrix with 10 independent rows or columns.

Having checked system observability, we propose an extended Kalman filter to observe the absolute orientation. The design of this extended Kalman filter is now described.

In practice, due to uncertainty in the determination of parameters and to angular measurement errors, system (3), and of course system (7), are only approximations. A standard solution is to represent modelling and measurement errors as additive noises disturbing the system.

Let us consider the associated "noisy" system:

$$x_{k+1} = f(x_k, \Gamma_k) + \alpha_k$$

$$y_k = C(x_k) = (\theta_1, \theta_2, \theta_3)^T + \beta_k$$

In the case of a linear system, if $\alpha_k$ and $\beta_k$ are white Gaussian noises, mutually independent and independent of $x$, the Kalman filter is an optimal estimator. When the system is not linear,
it is possible to use the extended Kalman filter (EKF) by linearizing the evolution equation $f$, and the observation equation (which is in our case linear) around the current state estimate. Although convergence and optimality are no longer guaranteed, the interest and the effectiveness of the extended Kalman filter have been proved in many experimental cases. The extended Kalman filter is very often used as a state observer (Bonnifait & Garcia 1998).

(a) Double support (half step $n$): The projection of the platform center is halfway between the leg tips.

(b) Double support (half step $n$): The projection of the platform center is closer to the back leg tip.

(c) Double support (half step $n$): The front leg is unbent just before take off (before the single support).

(d) Single support (half step $n$): Just after jump of the front leg, the front leg is bent.

(e) Single support (half step $n$): The distance between the leg tips is larger than in the previous double support phase.

(f) Double support (end of half step $n$ and start of half step $n+1$): Just after landing with an impact of the front leg. After half step $n$, the platform center has moved forward.

(g) Double support (half step $n+1$): The projection of the platform center is closer to the front leg tip.

(h) Double support (half step $n+1$): The back leg is unbent just before take off (before the next single support phase).

(i) Single support (half step $n+1$): Just after jump of the back leg, the back leg is bent.

(j) Single support (half step $n+1$): The distance between the leg tips is smaller than in the previous double support phase.

Fig. 4. Plot of half steps $n$ and $n+1$ of SemiQuad as a sequence of stick figures.
In the case of our system, the equations of the extended Kalman filter are:

- **a priori** estimation: uses data available before $t_{k+1}$
  \[
  \begin{align*}
  \hat{x}_{k+1} &= f(\hat{x}_k, \Gamma_k) \\
  P_{k+1} &= A_k P_k A_k^T + Q_a
  \end{align*}
  \] (14)

- **a posteriori** estimation: uses data available at $t_{k+1}$
  \[
  \begin{align*}
  \hat{x}_{k+1} &= \hat{x}_{k+1} + K_{k+1} (y_{k+1} - C \hat{x}_{k+1}) \\
  P_{k+1} &= (I_{100 \times 100} - K_{k+1} C) P_{k+1}^-
  \end{align*}
  \] (15)

with:
\[
A_k = \left( \frac{\partial f}{\partial \hat{x}} \right)_{\hat{x}=\hat{x}_k} \quad \text{and} \quad K_{k+1} = P_{k+1}^- C^T (C P_{k+1}^- C^T + Q_a)^{-1}
\]

Here $y_{k+1}$ are the measured joint variables, which are the first four components of vector $x_k$ at time $t_k$, and $C \hat{x}_{k+1}$ is the *a priori* estimation of these joint variables. $Q_a$ and $Q_v$ are the covariance matrices of $\alpha_k$ and $\beta_k$, $K$ is the Kalman gain and $P$ the estimated covariance matrix of prediction ($P^-$ at $t_k$) and estimation ($P$ at $t_k$) errors.

5. Simulation and experimental results.

For the simulation and experimental tests, the physical parameters defined in section 2 are used. The sampling period $\Delta$ is equal to 5 ms. The incremental encoders having $N=2000$ points per revolution, the variance of measurement is taken equal to $\frac{\pi^2}{3} \times 10^{-4}$.

The errors of incremental encoders being independent, we have chosen $Q_e = 8.225 \times 10^{-4} I_{1 \times 4}$.

The components of $Q_a$ for the configuration variables are determined by trial and error from simulation and experimental results. The components of $Q_v$ for velocity variables are derived from the values for position variables, taking into account the sampling period, and are larger than those corresponding to position variables.

\[
Q_a = \begin{bmatrix}
3.0 \times 10^{-10} I_{5 \times 5} & 0_{5 \times 3} \\
0_{5 \times 3} & 3.0 \times 10^{-7} I_{5 \times 5}
\end{bmatrix}
\]

The initialization of the covariance matrix $P$ takes into account a determination of $\alpha$ less precise and fixes the variances on the velocities, as for $Q_v$, taking into account of the sampling period.

\[
P_0 = \begin{bmatrix}
8 \times 10^{-1} I_{4 \times 4} & 0_{4 \times 1} & 0_{4 \times 1} \\
0_{4 \times 1} & 1.7 \times 10^{-5} I_{1 \times 1} & 0_{1 \times 5} \\
0_{4 \times 4} & 0_{1 \times 5} & 5 \times 10^{-2} I_{5 \times 5}
\end{bmatrix}
\]

All the tests in simulations and in experiments were done following the scheme of figure 5. In simulations, the joint variables $\theta_i$ and their velocities $\dot{\theta}_i$ ($i=1,2,3,4$) obtained by integration of the direct dynamic model of SemiQuad and the control torques $\Gamma_i$ ($i=1,2,3,4$) are the inputs of the extended Kalman filter. For the experimental tests, the joint variables $\theta_i$ ($i=1,2,3,4$) are measured and differentiated to obtain the velocities $\dot{\theta}_i$. These eight variables, together with
the four experimental torques \( \Gamma_i \) \( (i=1,2,3,4) \) are the inputs of the extended Kalman filter. In both cases, the state vector \( \mathbf{\theta} = [\theta_1, \dot{\theta}_1, \theta_2, \dot{\theta}_2, \theta_3, \dot{\theta}_3, \theta_4, \dot{\theta}_4, a, \dot{a}]^T \) is estimated.

\[ \begin{align*}
\Gamma_i \ (i=1,2,3,4) & \quad \text{\textbf{SemiQuad}} \quad \mathbf{\theta}, \dot{\mathbf{\theta}} \ (i=1,2,3,4) \\
\Gamma_i \ (i=1,2,3,4) & \quad \text{\textbf{Extended}} \quad \text{Kalman} \quad \mathbf{\hat{\theta}}, \dot{\mathbf{\hat{\theta}}} \ (i=1,2,3,4)
\end{align*} \]

Fig. 5. Principle of tests of the extended Kalman filter with SemiQuad.

5.1 Simulation results
Figure 6 shows the evolution of the estimated and real orientations of the platform during a single support phase of the cyclic walking gait of SemiQuad. The initial error, which has been set to 0.0262 rad (1.5 degree), is rapidly reduced, and the estimated orientation converges towards the real orientation. Let us notice that a maximum value of 1.5 degree for the initial error is reasonable because experimentally \( a(0) \) is determined by the geometric model at the end of the previous double support.

In the model used by the observer, we do not consider any friction. We have performed robustness tests of our estimator by adding a viscous friction, \( \Gamma_i = F_v \dot{\theta}_i \) \( (i=1,2,3,4) \), and a Coulomb friction \( \Gamma_i = F_s \dot{\theta}_i \) \( (i=1,2,3,4) \) to the simulation model. Figure 7 shows the estimated and real orientations of the platform of SemiQuad in the case when a viscous friction is added. The coefficient \( F_v \) equals to 0.1 N.m.s/rad. Similarly, figure 8 shows the estimated and the real orientations of the platform of SemiQuad in the case of a Coulomb friction, with a coefficient \( F_s \) equal to 0.2 N.m. Last robustness test (figure 9) presents the estimated and real orientations of the platform of SemiQuad with an inertia reduced by 5% for the platform in the simulator. In practice, 5% precision on inertia is feasible (see identification results in (Lydoire & Poignet 2003)).

From these robustness tests, we can conclude that we have no finite time convergence. However, the final relative errors of the estimated orientations of the platform of SemiQuad are small. Since it will be possible to update the initial condition of the estimator during the next double support phase, with the measurements of the encoders and the geometrical relations, such errors are not a problem.

5.2 Experimental results
At each step, the estimator is initialized with the configurations and the velocities at the end of the previous double support phase. At each sampling time, velocities are obtained
by the usual differentiation operation $\dot{\theta}_i = \frac{\theta_i(k\Delta) - \theta_i((k-1)\Delta)}{\Delta}$ ($i=1,2,3,4$). No filtering is applied to smooth the measured joint variables $\theta_i$, their velocities $\dot{\theta}_i$ and the four torques $\Gamma_i$ ($i=1,2,3,4$).

Fig. 6. Absolute orientation $\alpha(t)$ of the platform: real (solid) and estimated (dashed).

Fig. 7. Absolute orientation $\alpha(t)$ of the platform: real (solid) and estimated (dashed), with a supplement viscous friction.
Fig. 8. Absolute orientation $\alpha(t)$ of the platform: real (solid) and estimated (dashed), with a supplement Coulomb friction.

Fig. 9. Absolute orientation $\alpha(t)$ of the platform: real (solid) and estimated (dashed), with an error on the inertia of the platform.
Figure 10 shows the estimation of the absolute orientation of the platform $\alpha(t)$. The duration of the single support phase is 15% smaller than in simulation. It can probably be explained by the fact that our knowledge of the physical parameters of the robot is not perfect, and that we neglected effects such as friction in the joints.

Currently, there is no experimental measured data about the evolution of $\alpha(t)$ in single support, because SemiQuad is not equipped with a sensor such as a gyrometer or a gyroscope. However, in double support, using the geometric and kinematic models it is possible to calculate $\dot{\alpha}(t)$ and $\ddot{\alpha}(t)$. In addition to providing initial conditions for the observer, this also allows to calculate the orientation at the end of the single support phase, just after impact. The corresponding value is displayed as a star on the next graph, and is equal to 0.01 rad (0.57 degree). The difference between this value and the estimated value at the same instant is almost 3 degrees.

6. Conclusion

An application of the digital extended Kalman filter has been presented for the problem of estimating the absolute orientation of SemiQuad, a 2D dynamically stable walking robot. There are some differences between simulations and experiments, but the results still prove the ability of our observer to yield a short term estimation of the orientation of the robot. The precision is sufficient for the estimation to be useful for calculating the dynamic model and monitoring the balance of the robot. This task is important for SemiQuad, and vital for bipeds, to which the idea is also applicable (see Lebastard, Aoustin, & Plestan 2006 for a different type of observer). Given the possibility to re-initialize the observer at each double support phase, even if very short, as it can be for bipeds, the observer can provide the absolute orientation over time without the use of any additional sensor, which was the goal of our work.
In a near future, we plan to equip SemiQuad with a gyrometer to fully evaluate the performance of our estimator over time. Our perspective is to use the estimated orientation in advanced feedback controllers.

7. References

For many years, the human being has been trying, in all ways, to recreate the complex mechanisms that form the human body. Such task is extremely complicated and the results are not totally satisfactory. However, with increasing technological advances based on theoretical and experimental researches, man gets, in a way, to copy or to imitate some systems of the human body. These researches not only intended to create humanoid robots, great part of them constituting autonomous systems, but also, in some way, to offer a higher knowledge of the systems that form the human body, objectifying possible applications in the technology of rehabilitation of human beings, gathering in a whole studies related not only to Robotics, but also to Biomechanics, Biomimetics, Cybernetics, among other areas. This book presents a series of researches inspired by this ideal, carried through by various researchers worldwide, looking for to analyze and to discuss diverse subjects related to humanoid robots. The presented contributions explore aspects about robotic hands, learning, language, vision and locomotion.
