1. Introduction

The sensors in remote sensing systems are looking through a layer of atmosphere separating the sensors from the Earth’s surface being observed. It is essential to understand the effects of atmosphere on the electromagnetic radiation travelling from the Earth to the sensor through the atmosphere. The atmospheric constituents cause wavelength dependent absorption and scattering of radiation due to environment interactions, emissions and so on (fig. 1) [6]. The atmosphere between radiating surface and sensor can be understood as communication channel (CC). The technical conditions of CC during operation should be considered for the effective communications. Changes during data transfer can decrease the rate of data transmission in digital CC up to stop of transmission. In analog CC it can be cause distortions and noise of the transmitted signals. Some of the atmospheric effects can be corrected before the sensing data is subjected to further analysis and interpretation. These effects degrade the adequateness of received data. The new methods and supporting tools are developed to automate the measurement and consideration of the characteristics of the CC. It helps to build the information and mathematical models of nonlinear dynamic object such as the CC [3, 19, 20], i.e. to solve the identification problem.

Building Volterra models and using them for visualization for such complex nature effects as waves of sea surface were well studied in [8-10]. This methodic allows building linear and nonlinear models for different systems. Modern continuous CCs are nonlinear stochastic inertial systems. The model in the form of integral Volterra series used to identify them [3, 4]. The nonlinear and dynamic properties of such system are completely characterized by a sequence of multidimensional weighting functions – Volterra kernels).
Building a model of nonlinear dynamic system in the form of a Volterra series lies in the choice of the test actions form. Also it uses the developed algorithm that allows determining the Volterra kernels and their Fourier-images for the measured responses (multidimensional amplitude–frequency characteristics (AFC) and phase-frequency characteristics (PFC)) to simulate the CC in the time or frequency domain, respectively [16-18, 23].

The additional research of new method of nonlinear dynamical systems identification, based on the Volterra model in the frequency domain is proposed. This method lies in n–fold differentiation of responses of the identifiable system by the amplitude of the test polyharmonic signals. The developed identification toolkit is used to build information model of the test nonlinear dynamic system in the form of the first, second and third order model. [12, 13, 15, 20, 21]

The aim of this work is to identify the continuous CC using Volterra model in the frequency domain, i.e. the determination of its multi-frequency characteristics on the basis of the data of the input-output experiment, using test polyharmonic signals and interpolation method to obtain model coefficients [14, 16-19, 21].

2. Volterra models and identification of dynamical systems in the frequency domain

Generally, “input–output” type ratio for nonlinear dynamical system can be presented by Volterra series [19].

![Environment effects in remote sensing systems](image-url)
where the $n$–th partial component of response of the system is

$$y_n[x(t)] = \sum_{n=1}^{\infty} \int_{0}^{\infty} \cdots \int_{0}^{\infty} w_n(\tau_1, \ldots, \tau_n) \prod_{i=1}^{n} x(t-\tau_i) d\tau_i$$

$x(t)$ and $y(t)$ are input and output signals of system respectively; $w_n(\tau_1, \tau_2, \ldots, \tau_n)$ – weight function or $n$-order Volterra kernel; $y_n[x(t)]$ – $n$–th partial component of system’s response; $w_0(t)$ – denotes free component of the series (for zero initial conditions $w_0(t)=0$); $t$ – current time.

Commonly, the Volterra series are replaced by a polynomial, with only taking several first terms of series (1) into consideration. Nonlinear dynamical system identification in a form of Volterra series consists in $n$-dimensional weighting functions determination $w_n(\tau_1, \ldots, \tau_n)$ for time domain or it’s Fourier transforms $W_n(j\omega_1, \ldots, j\omega_n)$ – $n$–dimensional transfer functions for frequency domain.

Multidimensional Fourier transform for $n$-order Volterra kernel (1) is written in a form:

$$W_n(j\omega_1, \ldots, j\omega_n)=F_n[w_n(\tau_1, \ldots, \tau_n)]=\int_{0}^{\infty} \cdots \int_{0}^{\infty} \exp\left(-j \sum_{i=1}^{n} \omega_i \tau_i \right) \prod_{i=1}^{n} d\tau_i,$$

where $F_n$ – $n$–dimensional Fourier transform; $j=\sqrt{-1}$. Then the model of nonlinear system based on Volterra model in frequency domain can be represented as:

$$y[x(t)]=F^{-1}_n \left\{ W_n(j\omega_1, \ldots, j\omega_n) \prod_{i=1}^{n} X(j\omega_i) \right\} = \sum_{n=1}^{\infty} F^{-1}_n \left\{ W_n(j\omega_1, \ldots, j\omega_n) \prod_{i=1}^{n} X(j\omega_i) \right\} t_1=\ldots=t_n=t,$$

where $F^{-1}_n$ – inverse $n$–dimensional Fourier transform; $X(j\omega_i)$– Fourier transform of input signal.

Identification of nonlinear system in frequency domain consists in determination of absolute value and phase of multidimensional transfer function at given frequencies – multidimensional AFC $|W_n(j\omega_1, j\omega_2, \ldots, j\omega_n)|$ and PFC arg $W_n(j\omega_1, j\omega_2, \ldots, j\omega_n)$ which are defined by formulas:

$$|W_n(j\omega_1, \ldots, j\omega_n)| = \sqrt{\text{Re}[W_n(j\omega_1, \ldots, j\omega_n)]^2 + \text{Im}[W_n(j\omega_1, \ldots, j\omega_n)]^2},$$

$$\text{arg} W_n(j\omega_1, \ldots, j\omega_n) = \arctan \frac{\text{Im}[W_n(j\omega_1, \ldots, j\omega_n)]}{\text{Re}[W_n(j\omega_1, \ldots, j\omega_n)]}.$$
where Re and Im – accordingly real and imaginary parts of a complex function of \( n \) variables respectively.

**An approximation method** of identification of the nonlinear dynamical system based on Volterra series is offered [11, 14, 16-19]. During the identification of a Volterra kernel of \( m \)-th order significant effect on accuracy is rendered adjacent terms of a Volterra series. Therefore, it is necessary to apply the special methods, allowing minimizing this effect. The idea of such method lays in construction such expression of system responses to \( N (1 \leq m \leq N) \) test input signals with the given amplitudes that with certain accuracy (accurate within to the thrown terms of order \( N+1 \) and above) would be equal to \( m \)-th term Volterra series:

\[
y_m[x(t)] = \sum_{j=1}^{N} c_j y[a_j x(t)] = \sum_{n=1}^{\infty} \left( \sum_{j=1}^{N} c_j a_j^n \right) \int_0^{\infty} \cdots \int_0^{\infty} w_n(\tau_1, ..., \tau_n) \prod_{i=1}^n x(t - \tau_i) d\tau_i
\]

(4)

where \( a_i \) – amplitudes of test signals, random nonzero and pairwise different numbers; \( c_j \) – real coefficients which are chosen in such way that in a right part of (4) all first \( N \) terms are equal to 0, except \( m \)-th, and the multiplier at a \( m \)-multiple integral became equal to 1. This condition leads to a solution of the linear algebraic equations system concerning coefficients \( c_1, ..., c_N \):

\[
c_1 a_1 + c_2 a_2 + ... + c_N a_N = 0
\]

\[
... 
\]

\[
c_1 a_1^m + c_2 a_2^m + ... + c_N a_N^m = 1
\]

\[
... 
\]

\[
c_1 a_1^N + c_2 a_2^N + ... + c_N a_N^N = 0.
\]

(5)

This system (5) always has a solution, and the unique one, as the system determinant differs from Vandermonde determinant with only a multiplier \( a_1 a_2 ... a_N \). Thus, with any real numbers \( a_\rho \) that different from zero and pairwise different, it is possible to find such numbers \( c_j \) at which the linear combination (4) of system responses is equal to \( m \)-th term of a Volterra series accurate within to the thrown terms of series.

It is possible to build numberless assemblage of modes for expressions (4), by taking various numbers \( a_1, ..., a_N \) and defining (5) coefficients \( c_1, ..., c_N \) by them.

The choice of amplitudes \( a_i \) should provide the convergence of series (1) and an minimum error \( \Delta \) during extraction of a partial component \( y_m[x(t)] \) according to (4) defined by reminder of series (1) – terms of degree \( N+1 \) and above

\[
\sum_{j=1}^{N} c_j y[a_j x(t)] = \sum_{m=0}^{\infty} w_m(\tau_1, ..., \tau_m) \prod_{i=1}^m x(t - \tau_i) d\tau_i + \sum_{j=1}^{N} \sum_{m=N+1}^{\infty} y_n[a_j x(t)] = y_m[x(t)] + \Delta
\]

(6)
If \( x(t) \) – is a test effect with maximum admissible amplitude at which a series (1) converges, amplitudes \( a_j \) should be no more than 1 by their absolute values: \(|a_j| \leq 1\) for \( \forall j=1, 2, ..., N \).

The amplitudes of the test signals \( a_N^{(m)} \) and the corresponding coefficients \( c_N^{(m)} \) for responses are shown in table 1, where \( m \) – order of the estimated Volterra kernel; \( j \) – number of the experiment; \( N \) – approximation order, i.e. quantity of identification experiments.

Table 1. Numerical values of identification accuracy using approximation method

An interpolation method of identification of the nonlinear dynamical system based on Volterra series is offered \([12, 13, 15, 20, 21]\). It is used \( n \)-fold differentiation of a target signal on parameter-amplitude \( a \) of test actions to separate the response of the nonlinear dynamical system on partial components \( y_n[a x(t)] \).

**Affirmation 1.** Let at input of system test signal of \( a x(t) \) kind is given, where \( x(t) \) – is arbitrary function and \( a \) – is scale coefficient (amplitude of signal), where \( 0 < |a| \leq 1 \), then for the selection of a partial component of the \( n \)-th order \( y_n[a x(t)] \) from measurement of the response nonlinear system \( y[a x(t)] \) in the form of Volterra series, it is necessary to determine \( n \)-th partial derivative of the total response amplitude \( a \) where \( a=0 \)

\[
\hat{y}_n(t) = \sum_{\tau_1}^{\infty} \cdots \sum_{\tau_n}^{\infty} W_n(\tau_1, \ldots, \tau_n) \prod_{i=1}^{n} x(t - \tau_i) d\tau = \frac{1}{n!} \frac{\partial^n y[a x(t)]}{\partial a^n} \bigg|_{a=0}
\]

We use the method of extracting the partial components with the help of \( n \)-fold differentiation of the response \( y[a x(t)] \) with respect to parameter-amplitude \( a \) and the use of the derivative value at \( a=0 \).

Injecting an input signal \( a x(t) \) where \( a \) is the scaling factor (signal amplitude), one has the following response of the nonlinear system:
To distinguish the partial component of the n-th order, differentiate the system response n times with respect to the amplitude:

\[
\frac{\partial^n}{\partial a^n} y[a \cdot x(t)] = n! \int_0^t \ldots \int_0^t w_n(\tau_1, \ldots, \tau_n) \prod_{r=1}^{n+1} x(t-\tau_r) d\tau_r + \ldots
\]  

(9)

Taking the value of the derivative at \(a=0\), we finally obtain the expression for the partial component (7).

Formulas for numerical differentiation. Partial derivative should be substituted by form of finite difference for calculation. Differentiation of function, which was set in discrete points, could be accomplished by means of numerical computing after preliminary smoothing of measured results. Various formulas for the numerical differentiation are known, which differ from each other by means of error.

Let’s use universal reception which allows to substitute a derivative of any n order for differential ratio so that the error from such replacement for function \(y(a)\) was any beforehand set order of \(p\) approximation concerning a step of \(h=\Delta a\) of computational mesh on amplitude. Method of undetermined coefficient for equality

\[
\frac{d^n y(a)}{da^n} = \frac{1}{h^n} \sum_{r=-1}^{r_2} \sum_{r=1}^{r_1} c_r y(a+rh) + O(h^p),
\]  

(10)

where the coefficients \(c_r\) are taken not depending on \(h\), \(r = -r_1, -r_1 + 1, \ldots, -1, 0, 1, \ldots, r_2-1, r_2\), so that equality (10) was fair. Limits of summation \(r_1 \geq 0\) and \(r_2 \geq 0\) could be arbitrary, but so that the differential relation \(h^{-n} \sum c_r y(a + rh)\) of \(r_1 + r_2\) order have to satisfy to inequality \(r_1 + r_2 \geq 2n + p - 1\).

To define the \(c_r\) it is necessary to solve the following set of equations
If \( r_1 + r_2 = n + p - 1 \), then inscribed in \( n + p \) equality forms linear system concerning the same number of \( c_r \) unknown. The determiner of this system is Vandermonde's determiner and differs from zero. Thus, there is only one set of \( n \) coefficients, satisfying the system.

If \( r_1 + r_2 \geq n + p \), then there are many such sets of coefficients \( c_r \).

On the basis of (10) in [20] the formulas of derivative calculation of the first, second and third orders are received at \( a=0 \) with use of the central differences for equidistant nodes of the computational grid.

In work formulas for numerical differentiation with use of the central differences for equidistant assembly are used. Volterra kernel of the first order is determined by formulas as the first derivative at \( r_1 = r_2 = 1 \), \( r_1 = r_2 = 2 \) or \( r_1 = r_2 = 3 \) respectively.

\[
egin{align*}
    y'_0 &= \frac{1}{2h}(-y_{-1} + y_1), \\
    y'_0 &= \frac{1}{12h}(y_{-2} - 8y_{-1} + 8y_1 - y_2), \\
    y'_0 &= \frac{1}{60h}(-y_{-3} + 9y_{-2} - 45y_{-1} + 45y_1 - 9y_2 + y_3).
\end{align*}
\]

Volterra kernel of the first order is determined by formulas as the first derivative at \( r_1 = r_2 = 1 \), \( r_1 = r_2 = 2 \) or \( r_1 = r_2 = 3 \) respectively

\[
egin{align*}
    y''_0 &= \frac{1}{h^2}(y_{-1} - 2y_0 + y_1), \\
    y''_0 &= \frac{1}{12h^2}(-y_{-2} + 16y_{-1} - 30y_0 + 16y_1 - y_2), \\
    y''_0 &= \frac{1}{180h^2}(2y_{-3} - 27y_{-2} + 270y_{-1} - 490y_0 + 270y_1 - 27y_2 + 2y_3).
\end{align*}
\]
Volterra kernel of the first order is determined by formulas as the first derivative at \( r_1=r_2=2 \) or \( r_1=r_2=3 \) respectively

\[
\begin{align*}
y_0'' &= \frac{1}{2h^3} \left( -y_{-2} + 2y_{-1} - 2y_1 + y_2 \right), \\
y_0''' &= \frac{1}{8h^3} \left( y_{-3} - 8y_{-2} + 13y_{-1} - 13y_1 + 8y_2 - y_3 \right).
\end{align*}
\] (14)

In the formulas written above, we use the following notations

\[
y'_{0} = y'(0), \quad y''_{0} = y''(0), \quad y'''_{0} = y'''(0); \quad y_r(y(rh), \ r = 0, \pm 1, \pm 2, \pm 3)
\]

where we put \( y_0=0 \), since identification nonlinear systems is implemented with zero initial conditions. The test polyharmonic effects for identification in the frequency domain representing by signals of such type:

\[
x(t) = \sum_{k=1}^{n} A_k \cos(\omega_k t + \varphi_k),
\] (15)

where \( n \) – the order of transfer function being estimated; \( A_k, \omega_k \) and \( \varphi_k \) – accordingly amplitude, frequency and a phase of \( k \)-th harmonics. In research, it is supposed every amplitude of \( A_k \) to be equal, and phases \( \varphi_k \) equal to zero.

For identification in the frequency domain the test polyharmonic signals are used. We prove:

**Statement.** If test polyharmonic signal is used in form

\[
x(t) = A \sum_{k=1}^{n} \cos(\omega_k t + \varphi_k) = A \left( \sum_{k=1}^{n} e^{j\omega_k t} + e^{-j\omega_k t} \right)
\] (16)

then the \( n \)-th partial component of the response of test system can be written in form:

\[
y_n(t) = \frac{A^n}{2^{n-1}} E(n/2) \sum_{m=0}^{n} C_n^m \sum_{k=1}^{n} \sum_{l=m+1}^{n} | W_n(-j\omega_{k_1} \ldots -j\omega_{k_m}, j\omega_{k_{m+1}} \ldots j\omega_{k_n}) | \times
\]
\[
\times \cos \left( \left( -\sum_{k=1}^{m} \omega_{k_1} \ldots \sum_{l=m+1}^{n} \omega_{k_l} \right) t + \arg W_n(-j\omega_{k_1} \ldots -j\omega_{k_m}, j\omega_{k_{m+1}} \ldots j\omega_{k_n}) \right),
\] (17)

where \( E(n/2) \) – function used to obtain the of integer part of the value.

The component with frequency \( \omega_1+\ldots+\omega_n \) is extracted from the response to test signal (15):
Certain limitations should be imposed while choosing of frequency polyharmonic test signals in a process determining multidimensional AFC and PFC. This is the reason why the values of AFC and PFC in this unallowable points of multidimensional frequency space can be calculated using interpolation only. In practical realization of nonlinear dynamical systems identification it is needed to minimize number of such undefined points at the range of multidimensional frequency characteristics determination. This was performed to provide a minimum of restrictions on choice of frequency of the test signal. It is shown that existed limitation can be weakened. New limitations on choice of frequency are reducing number of undefined points.

After analyzing the (18) it is defined: to obtain Volterra kernels for nonlinear dynamical system in frequency domain the limitations on choice of frequencies of test polyharmonic signals have to be restricted. These restrictions provide inequality of combination frequencies in the test signal harmonics. The theorem about choice of test signals frequencies is proven.

The theorem about choice of test signals frequencies. For the definite filtering of a response of the harmonics with combination frequencies \( \omega_1+\omega_2+\ldots+\omega_n \) within the \( n \)-th partial component it is necessary and sufficient to keep the frequency from being equal to another combination frequencies of type \( k_1\omega_1+\ldots+k_n\omega_n \), where the coefficients \( \{k_i\mid i=1, 2, \ldots, n\} \) must satisfy the conditions:

- number \( K \) of negative value coefficients \( (k_i<0) \) is in \( 0\leq K \leq E(n/2) \) (where \( E \) – function used to obtain the of integer part of the value);

\[
\sum_{i=1}^{n} |k_i| \leq n;
\]

\[
\sum_{i=1}^{n} |k_i| = n \pmod{2}, n - \sum_{i=1}^{n} |k_i| = 2l, \ l\in N.
\]

It was shown that during determination of multidimensional transfer functions of nonlinear systems it is necessary to consider the imposed constraints on choice of the test polyharmonic signal frequencies. This provides inequality of combination frequencies in output signal harmonics: \( \omega_1\neq0, \omega_2\neq0 \) and \( \omega_1\neq\omega_2 \) for the second order identification procedure, and \( \omega_1\neq0, \omega_2\neq0, \omega_3\neq0, \omega_1\neq\omega_3, \omega_2\neq\omega_3, 2\omega_1\neq\omega_3+\omega_2, 2\omega_2\neq\omega_3+\omega_1, 2\omega_3\neq\omega_2+\omega_1, 2\omega_1\neq\omega_2-\omega_3, 2\omega_2\neq\omega_1-\omega_3, 2\omega_3\neq-\omega_1+\omega_2, 2\omega_1\neq-\omega_2+\omega_3 \) for the third order identification procedure.

The amplitudes of the test signals \( a_i^{(n)} \) and the corresponding coefficients \( c_i^{(n)} \) for responses are shown in Table 2, where \( n \) – order of the estimated Volterra kernel; \( i \) – number of the experiment \( (i=1, 2, \ldots, N) \), where \( N=r_1+r_2 \), i.e. number of interpolation knots (number of experiments).
Described method was tested using nonlinear test system (fig. 2) represented by Riccati equation

\[ \frac{dy(t)}{dt} + \alpha y(t) + \beta y^2(t) = u(t). \]  (19)

3. The techniques of test system identification

Described method was tested using nonlinear test system (fig. 2) represented by Riccati equation

Figure 2. Simulink–model of the test system
Analytical expressions of AFC and PFC for the first, second and third order model were received:

\[ |W_1(j\omega)| = \frac{1}{\sqrt{\alpha^2 + \omega^2}}, \quad \text{arg}W_1(j\omega) = -\arctg \frac{\omega}{\alpha}; \]

\[ |W_2(j\omega_1, j\omega_2)| = \frac{\beta}{\sqrt{(\alpha^2 + \omega_1^2)(\alpha^2 + \omega_2^2)[\alpha^2 + (\omega_1 + \omega_2)^2]}}; \]

\[ \text{arg}W_2(j\omega_1, j\omega_2) = -\arctg \frac{(2\alpha^2 - \alpha^2\omega_1\omega_2)(\omega_1 + \omega_2)}{\alpha(\alpha^2 - \omega_1\omega_2 - \alpha(\omega_1 + \omega_2)^2)}; \]

\[ |W_3(j\omega_1, j\omega_2, j\omega_3)| = \sqrt{\frac{[\text{Re}(W_3(j\omega_1, j\omega_2, j\omega_3))]^2 + [\text{Im}(W_3(j\omega_1, j\omega_2, j\omega_3))]^2}{\sqrt{\alpha^2 + (\omega_1 + \omega_2 + \omega_3)^2}[\alpha^2 + (\omega_1 + \omega_2)^2][\alpha^2 + (\omega_1 + \omega_3)^2][\alpha^2 + (\omega_2 + \omega_3)^2]}}; \]

\[ \text{arg}W_3(j\omega_1, j\omega_2, j\omega_3) = \arctg \frac{\text{Im}W_3(j\omega_1, j\omega_2, j\omega_3)}{\text{Re}W_3(j\omega_1, j\omega_2, j\omega_3)} = -\arctg \frac{DA-\beta C}{AB + CD}, \]

where

\[ u = \alpha^2 - \alpha\omega_1\omega_2 - \alpha\omega_2\omega_3 - \alpha(\omega_1 + \omega_2 + \omega_3); \]

\[ v = (\omega_1 + \omega_2 + \omega_3)(2\alpha^2 - \alpha\omega_1\omega_2 - \omega_2\omega_3); \]

\[ w = (\alpha^2 - \omega_1\omega_2 - \omega_2\omega_3)(\omega_2 - \omega_1\omega_2 - \omega_1\omega_3) + \alpha^2(\omega_1 + \omega_2 + \omega_3)^2; \]

\[ x = \alpha(\omega_1 + \omega_2 + \omega_3)(2\alpha^2 - 2\omega_1\omega_2 - \omega_1\omega_3 - \omega_2\omega_3). \]

The main purpose was to identify the multi-frequency performances characterizing nonlinear and dynamical properties of nonlinear test system [11–21]. Volterra model in the form of the 1st, 2nd and 3rd order polynomial is used. Thus, test system properties are characterized by transfer functions of \( W_1(j\omega) \), \( W_2(j\omega_1, j\omega_2) \), \( W_3(j\omega_1, j\omega_2, j\omega_3) \) – by Fourier-images of weight functions \( w_1(t) \), \( w_2(t_1, t_2) \) and \( w_3(t_1, t_2, t_3) \).

Structure charts of identification procedure – determinations of the 1st, 2nd and 3rd order AFC of CC are presented accordingly in figs. 3–5.

The weighted sum is formed from received signals – responses of each group from figs. 3–5.

As a result the partial components of CC responses \( y_1(t) \), \( y_2(t) \) and \( y_3(t) \) are got. For each partial component of response the Fourier transform (the FFT is used) is calculated, and from received spectrum only an informative harmonics (which amplitudes represent values of required characteristics of the first, second and third orders AFC) are taken.
The first order AFC $|W_1(j\omega)|$ and PFC arg$W_1(j\omega)$ is received by extracting the harmonics with frequency $\omega$ from the spectrum of the CC partial response $y_1(t)$ to the test signal $x(t)=(A/2)\cos\omega t$.

The second order AFC $|W_2(j\omega, j(\omega+\Omega_1))|$ and PFC arg$W_2(j\omega, j(\omega+\Omega_1))$ having $\omega_1=\omega$ and $\omega_2=\omega+\Omega_1$ were received by extracting the harmonics with summary frequency $\omega_1+\omega_2$ from the spectrum of the CC partial response $y_2(t)$ to the test signal $x(t)=(A/2)(\cos\omega_1 t+\cos\omega_2 t)$.

The third order AFC $|W_3(j\omega, j(\omega+\Omega_1), j(\omega+\Omega_2))|$ and PFC arg$W_3(j\omega, j(\omega+\Omega_1), j(\omega+\Omega_2))$ having $\omega_1=\omega$, $\omega_2=\omega+\Omega_1$, and $\omega_3=\omega+\Omega_2$ were received by extracting the harmonics with summary frequency $\omega_1+\omega_2+\omega_3$ from the spectrum of the CC partial response $y_3(t)$ to the test signal $x(t)=(A/2)(\cos\omega_1 t+\cos\omega_2 t+\cos\omega_3 t)$.

The results (first, second and third order AFC and PFC which had been received after procedure of identification) are represented in figs. 6–8.
Figure 5. The structure chart of identification using 3rd order Volterra model in frequency domain, number of experiments $N=6$: $a_1=-3h$, $a_2=-2h$, $a_3=h$, $a_4=2h$, $a_5=3h$; $c_1=-1/8$, $c_2=-1$, $c_3=13/8$, $c_4=-13/8$, $c_5=1$, $c_6=1/8$

Figure 6. First order AFC and PFC of the test system: analytically calculated values (1), section estimation values with number of experiments for the model $N=4$ (2)
Figure 7. Second order AFC and PFC of the test system: analytically calculated values (1), sub-diagonal cross-section values with number of experiments for the model \( N=4 \) (2), \( \Omega_1=0.01 \text{ rad/s} \)

Figure 8. Third order AFC and PFC of the test system: analytically calculated values (1), sub-diagonal cross-section values with number of experiments for the model \( N=6 \) (2), \( \Omega_1=0.01 \text{ rad/s}, \Omega_2=0.1 \text{ rad/s} \)

The second and third order surfaces for AFC and PFC received after procedure of the test system identification are shown in fig. 9 and fig. 10 respectively.
Figure 9. Surface of the test system AFC (left) and PFC (right) built of the second order subdiagonal cross-sections received for $N=4$.

Figure 10. Surface of the test system AFC (left) and PFC (right) built of the third order subdiagonal cross-sections received for $N=6$, $\omega_3=0.1$ rad/s.

Presented surfaces are built from sub–diagonal cross-sections which were received separately. $\Omega_1$ was used as growing parameter of identification with different value for each cross-section in second order characteristics. Fixed value of $\Omega_2$ and growing value of $\Omega_1$ were used as parameters of identification to obtain different value for each cross-section in third order characteristics.

Numerical values of identification accuracy using interpolation method for the test system are represented in table 3, where: $n$ – order of the estimated Volterra kernel, $N$ – approximation order/number of interpolation knots (number of experiments).
Comparison of the numerical values for identification accuracy using interpolation method [17-18] and approximation one [13-16] for the test system is presented in table 4.

4. The study of noise immunity of the identification method

Experimental researches of the noise immunity of the identification method were made. The main purpose was the studying of the noise impact (noise means the inexactness of the
measurements) to the characteristics of the test system model using interpolation method in frequency domain.

The first step was the measurement of the level of useful signal (harmonic cosine test signal shown in fig. 11a) after test system (Out2 in fig. 12). The amplitude of this signal was defined as the 100% of the signal power.

After that procedure the Random Noise signal (with the form shown in fig. 11b) where added to the test system output signal. This steps where performed to simulate inexactness of the measurements in the model. The sum of these two signals for the linear test model signal is shown in fig. 13.

Figure 11. a) Test signal and b) random noise with 50% amplitude of test signal

Figure 12. The Simulink model of the test system with noise generator and osillosopes

The simulations with the test model were performed. Different noise levels were defined for different order of the Volterra model.

The adaptive wavelet denoising was used to reduce the noise impact on final characteristics of the test system. The Daubechie wavelet of the 2 and 3 level was chosen (fig. 14) and used for the AFC and PFC denoising respectively [2, 5, 7].
The first order (linear) model was tested with the level of noise 50% and 10% and showed excellent level of noise immunity. The noised (fig. 15a) and de-noised (filtered) (fig. 15b) characteristics (AFC and PFC) with level of noise 50% are presented.

The second order (nonlinear) model was tested with the level of noise 10% and 1% and showed good level of noise immunity. The noised (fig. 16a) and de-noised (filtered) (fig. 16b) characteristics (AFC and PFC) with level of noise 10% are presented.

Figure 16. Noised (a) and denoised (b) characteristics (AFC – top, PFC – bottom) of the 2\textsuperscript{nd} order model of the test system with level of noise 10%.
The third order (nonlinear) model was tested with the level of noise 10% and 1% and showed good level of noise immunity. The noised (fig. 17a) and de-noised (filtered) (fig. 17b) characteristics (AFC and PFC) with level of noise 1% are presented.

Table 5. Standard deviation for interpolation method with noise impact (bold font shows the best values)

The diagrams showing the improvement of standard deviation for identification accuracy using the adaptive wavelet denoising of the received characteristics (AFC and PFC) are shown in fig. 18 and fig. 19 respectively.

![Figure 18](http://dx.doi.org/10.5772/58354)
5. The technique and hardware-software tools of radiofrequency CC identification

Experimental research of the Ultra High Frequency range CC were done. The main purpose was the identification of multi-frequency characteristics that characterize nonlinear and dynamical properties of the CC. Volterra model in the form of the second order polynomial is used. Thus physical CC properties are characterized by transfer functions of $W_1(j2\pi f)$, $W_2(j2\pi f_1j2\pi f_2)$ and $W_3(j2\pi f_1,j2\pi f_2,j2\pi f_3)$ – by the Fourier-images of weighting functions $w_1(t)$, $w_2(t_1,t_2)$ and $w_3(t_1,t_2,t_3)$.

Implementation of identification method on the IBM PC computer basis has been carried out using the developed software in Matlab software. The software allows automating the process of the test signals forming with the given parameters (amplitudes and frequencies). Also this software allows transmitting and receiving signals through an output and input section of PC soundcard, to produce segmentation of a file with the responses to the fragments, corresponding to the CC responses being researched on test polyharmonic effects with different amplitudes.

In experimental research two identical marine transceivers S.P.RADIO A/S SAILOR RT2048 VHF (the range of operational frequencies is 154,4–163,75 MHz) and IBM PC with Creative Audigy 4 soundcards were used. Sequentially AFC of the first and second orders were defined. The method of identification with number of experiments $N=4$ was applied. Structure charts
of identification procedure – determinations of the 1st, 2nd and 3rd order AFC of CC are presented accordingly in figs. 3–5. The general scheme of a hardware–software complex of the CC identification, based on the data of input–output type experiment is presented in fig. 20.

The CC received responses $y[a_i x(t)]$ to the test signals $a_i x(t)$, compose a group of the signals, which amount is equal to the used number of experiments $N (N=4)$, shown in fig. 21. In each following group the signals frequency increases by magnitude of chosen step. A cross-correlation was used to define the beginning of each received response.

![Figure 20. The general scheme of the experiment](http://dx.doi.org/10.5772/58354)

Maximum allowed amplitude in described experiment with use of sound card was $A=0.25V$ (defined experimentally). The range of frequencies was defined by the sound card pass band ($20...20000$ Hz), and frequencies of the test signals has been chosen from this range, taking into account restrictions specified above. Such parameters were chosen for the experiment: start frequency $f_s=125$ Hz; final frequency $f_e=3125$ Hz; a frequency change step $F=125$ Hz; to define AFC of the second order determination, an offset on frequency $F_1=f_2-f_1$ was increasingly growing from 201 to 3401 Hz with step 100 Hz.

The weighed sum is formed from received signals – responses of each group (figs. 3–5). As a result we get partial components of the response of the CC $y_1(t)$ and $y_2(t)$. For each partial component of the response a Fourier transform (the Fast Fourier Transform is used) is calculated. Only informative harmonics (which amplitudes represents values of required characteristics of the first, second and third order AFC) are taken from received spectrum.

The first order amplitude-frequency characteristic $|W_1(j2\pi f)|$ is received by extracting the harmonics with frequency $f$ from the spectrum of the partial response of the CC $y_1(t)$ to the test signal $x(t)=(A/2)\cos2\pi ft$. 
The second order AFC \( |W_2(j2\pi f_1, j2\pi f_2)| \), where \( f_1=f \) and \( f_2=f+F_1 \) was received by extracting the harmonics with summary frequency \( f_1+f_2 \) from the spectrum of the partial response of the CC \( y_2(t) \) to the test signal \( x(t) = (A/2)(\cos2\pi f_1 t + \cos2\pi f_2 t) \).

The third order AFC \( |W_3(j2\pi f_1, j2\pi f_2, j2\pi f_3)| \), where \( f_1=f, f_2=f+F_1 \) and \( f_3=127.5 \) Hz were received by extracting the harmonics with summary frequency \( f_1+f_2+f_3 \) from the spectrum of the partial response of the CC \( y_3(t) \) to the test signal \( x(t) = (A/2)(\cos2\pi f_1 t + \cos2\pi f_2 t + \cos2\pi f_3 t) \).

The wavelet noise-suppression was used to smooth the output data of the experiment [9]. The results received after digital data processing of the data of experiments (wavelet “Coiflet” denoising) for the first, second and third order AFC are presented in fig. 22–25.

The surfaces shown in fig. 24-25 are built from sub-diagonal sections that are received separately. We used \( F_1 \) as growing parameter of identification with different value for each section.
Figure 22. AFC of the first order after wavelet “Coiflet” 2nd level noise-suppression

6. Conclusion

Communication channel as a media for remote sensing systems functioning is analyzed. Nonlinear effects of the environments have great impact on result data received in experiments. The method based on Volterra model using polyharmonic test signals for identification nonlinear dynamical systems is analyzed. To differentiate the responses of system for partial components we use the method based on linear combination of responses on test signals with different amplitudes.

New values of test signals amplitudes were defined and they are greatly raising the accuracy of identification compared to amplitudes and coefficients written in [1]. The accuracy of identification of nonlinear part of the test system growth 2 times and the standard deviation in this case is about 5%.

The interpolation method of identification using the hardware methodology written in [5] is applied for construction of informational Volterra model as an APC of the first and second order for UHF band radio channel.

Received results reveal essential nonlinearity of the CC that leads to distortions of signals in radio broadcasting devices, reduces the important indicators of the TCS: accuracy of signals reproduction, throughput, noise immunity.

The noise immunity is very high for the linear model, high enough for the second order nonlinear model and has moderate noise immunity for the third order model. The wavelet denoising is very effective and gives the possibility to improve the quality of identification of the noisy measurements up to 1.54 and 4.07 times for the AFC and PFC respectively.

Final characteristics of the CC have to be used to maintain sensor systems to improve the adequateness of received data.
